Where a particularly white nitrocellulose for colorless or water-white solutions is required, the pulp is given a bleaching treatment with any of the well-known bleaching agents, such as bleaching powder, sodium hypochlorite or permanganate and oxalic acid. It is essential that whatever bleach is used all traces of it must be thoroughly washed out. After the purification treatment the pulp is washed and the water is reduced to about 30 per cent by wringing the pulp in centrifugal machines. Sometimes a wet machine such as is common in the paper industry is used, but this does not reduce the moisture to the same extent.

DEHYDRATION WITH ALCOHOL

In order to remove the last 30 per cent of water, the nitrocellulose was formerly dried by means of hot air. This was a dangerous proceeding, as it was inevitable that dust would accumulate in corners or on steam pipes, where it would gradually decompose and finally take fire, usually causing the loss of the whole house. This drying is now done by means of alcohol, as alcohol is a constituent of most solvents, and where it is not a solvent, the small quantity remaining does no harm. Dehydration by alcohol may be carried on in several ways. The usual method employs a hydraulic press. The equivalent of 50 lb. of dry nitrocellulose, but in the wet condition, is placed in the cylinder of a hydraulic press and compressed to a cake 16 in. in diameter and about 8 in. high, a pressure of about 250 lb. being used. (See Fig. 5.)

FIG. 5. DEHYDRATING PRESS SHOWING CAKE READY FOR TREATMENT WITH ALCOHOL

FIG. 6. CONVEYOR CARRYING NITROCELLULOSE TO FINAL PACKING HOUSE

Seventy-five lb. of strong alcohol is then pumped through the cake, being uniformly distributed over it by perforations in the top piston. Actual displacement of the water takes place, as can be shown by taking samples of the discharge. When all this alcohol has been pumped in, the block is saturated with strong alcohol in place of water, and the excess is removed by applying a pressure of 3,500 lb. for a short time. The whole operation with experienced operators takes less than four minutes, and it is therefore the quickest and most efficient method. When the block is removed from the press it contains from 20 to 25 per cent of alcohol, depending on the length of pressing and the character of the nitrocellulose. The block is now broken up in order to make the individual particles more accessible to solvents, and is ready for any of its various uses. Nitrocellulose is not dehydrated for use in gelatine dynamite or charges for torpedoes and mines. In the former case the small percentage of moisture, amounting to perhaps 0.3 per cent of the weight of the dynamite, does not make any difference. In the latter the guncotton is compressed under very high pressure, thus reducing the moisture to about 12 per cent. Guncotton with this percentage of moisture can be detonated by the detonation of a small quantity of dry guncotton.

MILITARY AND PEACE-TIME USES

The uses of nitrocellulose are many and varied. There is probably not a household that does not contain it in one form or another, nor would the World War have been possible on its enormous scale without nitrocellulose powders. As previously mentioned, its first uses were in medicine and in photography, and these uses still continue and have in the latter case reached enormous proportions. Most moving picture and camera films are made from it, and photographic papers receive a preliminary treatment with nitrocellulose solutions. Collodion is still used as the carrier for the sensitive emulsion used in photo-engraving.

During the years of the World War, of course, its largest use was for smokeless powders. Before the war the total capacity of the country for cannon powder was probably not far in excess of 40,000 lb. per day, or 12,000,000 lb. annually. At the time the armistice was signed facilities had been provided to turn out this quantity in less than four days. Most of

the plants that produced this enormous quantity have since been dismantled. Military smokeless powders consist of nitrocellulose alone or of a mixture of nitroglycerine and nitrocellulose. Most countries outside of Great Britain use the former, but even Great Britain was forced to come to it during the war.

One of the largest peace-time uses for nitrocellulose is found in the celluloid or pyroxylin plastic industry. Celluloid, being a trade name protected by registration in the Patent Office, other manufacturers sell this product under such names as Fiberloid, Viscoloid, Pyralin and Herculoid, etc. The methods of manufacture used by the different companies are very similar. The nitrocellulose is prepared with few exceptions, at least in this country, from a pure rag tissue paper. It can, however, be made successfully from cotton. The main consideration is to get a raw material that is clean.

Other important uses are found in the artificial leather and lacquer industries. The first artificial silk was made from nitrocellulose, and fiber silk of this type still holds its own against more recent processes as shown by the construction of a plant for its manufacture in this country within the past year. Nitrocellulose is also used in a variety of other ways such as in solid alcohol, gas mantles, nail polishes and as a coating for gas mantles.

From this brief outline some idea of the importance and magnitude of the nitrocellulose industry and of the interesting problems connected with it should be conveyed. The nitrocellulose industry is based on cellulose, and cellulose itself presents a great many problems. As has been mentioned before, its constitution or chemical structure is still unknown. It has been pointed out elsewhere that original American contributions to cellulose chemistry have been very few. To encourage research and discussion in this field a Cellulose Section has been established by the American Chemical Society. It is hoped that all who are interested in this subject will enroll in this section and take part in future meetings, which should prove profitable and interesting.

Lead and Zinc Pigments Marketed in the United States, 1919-20

The following table shows the amount of lead and zinc pigments marketed in the United States in 1920, with the value and average selling price of each, compiled from reports made by producers to the United States Geological Survey, Department of the Interior. Figures for 1919 are also shown for comparison.

An increase in the quantity sold was shown by every product except zinc oxide, in which there was a loss of 15 per cent, but the average price per ton of zinc oxide showed a slight gain. There was also an increase in the average selling price of the other pigments. The greatest gains in 1920 were made by litharge, in which the gain in sales was 33 per cent and the gain in average price per ton was \$61.11, or 44 per cent.

LEAD AND ZINC PIGMENTS MARKETING IN THE UNITED STATES, 1919-20

	1919			1920		
	Quantity, (Short Tons)	Value Total	Per Ton	Quantity, (Short Tons)	Value Total	Per Ton
White lead:

Chemical Dips Prevent Blue Stain in Lumber*

Blue stain is the most troublesome of the sap stains which discolor wood. It is caused by a fungus which germinates on the sapwood and penetrates its cells in search of starches and sugars. This action of the fungus causes no perceptible weakening of the wood, but the discoloration which results lessens the value of the lumber for many purposes, such as interior finish, flooring and basket and box veneers. The stain at first may be no more than a bluish spot or stream on the surface, but later, as the fungus develops, the discoloration may involve all of the sapwood and become too deep to surface off. The blue-stain fungus can revive in timbers after long periods of inaction brought on by lack of moisture.

GREEN LUMBER MOST AFFECTED

Warm weather and a comparatively high moisture content of the wood are the most favorable conditions for the growth of the blue-stain fungus. Most of the infection occurs in green lumber which is piled without ample ventilation between the boards in the mill yard or during shipment.

As yet no absolutely dependable means of preventing blue stain has been found, other than kiln drying the lumber. The ordinary kiln-drying process is entirely effective against blue stain, but there are many cases in which this means of prevention is not feasible. Staining during air seasoning can be largely controlled by open piling. This affords free circulation of the air and so hastens drying, but not always sufficiently under adverse weather conditions to discourage the stain fungi.

CHEMICALS USED TO PREVENT STAIN

The treatment of the green lumber with antiseptic dips is the most effective method which is generally applicable at the present time. For this purpose the chemicals commonly used are sodium carbonate and sodium bicarbonate. Neither is a sovereign remedy under severe conditions, such as continuous rainy periods during the warm months, but will go far towards keeping the stock clean. In rainy seasons an 8 per cent solution of sodium carbonate is desirable, but in drier weather half this strength should suffice. A high grade of soda ash should contain about 58.5 per cent alkali, and every effort should be made to conform to this standard of purity. When sodium bicarbonate is used, an 11 per cent solution should be employed in wet weather and 5 to 6 per cent in dry weather. This chemical when dry should contain about 37 per cent alkali.

POINTS TO BEAR IN MIND

In the use of these chemical dips, the following points should be kept in mind: The solutions should be carefully mixed and the concentrations in the dipping tanks should be kept uniform by means of a hydrometer; the solutions should be heated when applied, the bicarbonate solution not above 120 deg. F., however, because it is broken into the carbonate by excessive heating; the stock should be dipped as it comes from the saw; after dipping it should be carefully piled so as to insure ample ventilation. Narrow, chemically treated cross strips are preferable to the wide untreated strips commonly employed, since treated crossers tend to eliminate stain at the point of contact.

Some Points in the Design of Blast-Furnace Gas Cleaners*

Methods for Determining the Velocity and Moisture Content of Hot Gases Flowing Through Large Pipes
—Calculations for a Heat Interchanger Built to Cool Gas From a Ferromanganese Furnace at
1,200 Deg. F. to 400 Deg. F. Without Increasing Its Absolute Humidity

BY N. H. GELLERT
President Gellert Engineering Co.

THE problem of cleaning gases issuing from a blast furnace has never been a simple one. Various methods of cleaning gases have been discussed so thoroughly in papers which have been read in the past before technical societies interested in this general subject that there is no need of reviewing this subject again at this time.

It is of course essential in the very beginning to know the condition of the blast-furnace gas before there can be any intelligent attempt to clean the dust and fume from the gas. In general, blast-furnace gases contain from 2 to 10 grains of dust per cu.ft. of gas at standard conditions of temperature and pressure—namely, 62 deg. F. and 29.92 in. Hg. This dust exists in the form of both dust and fume. The fume is so finely subdivided, however, that in a great many respects it acts as a perfect gas.

In order to determine how to apply a cleaner to the blast-furnace gas, there are at least four things which must be investigated: Velocity and volume, dust content, moisture content and temperature.

The equipment necessary to make a volume determination, as a rule, is a Pitot tube of a standard type, a manometer tube, rubber tubing, some boards and nails, measuring rule and a few tools. A gas-measuring station location should be selected in the gas main where the most uniform gas flow conditions are ap-

the circular main should then be calculated. The velocity of the gas flowing through the main is greater at the center than near the walls. Therefore to get the average gas velocity it is necessary to take a large number of velocity readings across one or preferably two diameters of the main. By dividing the main into equal areas as in Tables I and II it is possible to get the average main velocity in the simplest way and with the least expenditure of time. The average velocity of the total gas flow will be the average of the velocities at the mean velocity points of the equal area zones.

TABLE II. DIAMETER AND RADII OF CONCENTRIC RINGS FOR FIVE EQUAL AREAS

Area	Diameter of Outer Edge of Ring	Mean Velocity Point	
		Distance From Center	Distance From Sides of Pipe
1	44.7	15.8	34.2 and 65.8
2	63.2	27.4	22.6 and 77.4
3	77.5	35.4	14.7 and 85.3
4	89.4	41.8	8.2 and 91.8
5	100.0	47.4	2.6 and 97.4

Under normal conditions the following formula applies to blast-furnace gases.

$$V = 2.9\sqrt{TH}$$

Where

V is the gas velocity in ft. per sec.;

T is temperature in deg. F. plus 460, and

H is velocity head in inches of water.

There have been two methods developed for determining the vapor volume and the resulting volume of the gas mixture. Both methods check within 10 per cent for moisture and within less than 1 per cent for totals of gas and moisture. The formula resulting from one of these methods is:

$$V_f = V_w \times \frac{V_s}{T_s} \times T_f + V_m \times \frac{T_f}{T_m} \times \frac{P_m}{P_f}$$

Where

V_f is volume of gas at conditions in main in cu.ft.;

V_w is volume of vapor at main conditions in cu.ft.;

V_m is volume of dry gas at meter conditions in cu.ft.;

T_f is absolute temperature at main conditions;

T_m is absolute temperature of gas at meter;

T_s is absolute temperature of the saturated vapor or steam at the pressure of gas main;

P_m is absolute pressure of meter in inches of mercury. It equals $B - P_m$ if pressure is negative (B is 29.92 in. Hg when standard);

P_f is absolute pressure of gas main or flue. It equals $B + P_f \times 0.0735$ if pressure is positive;

P_f is absolute pressure in inches of water in flue or main;

V_g is the vol. of dry gas at main conditions in cu.ft.;

V_s is specific volume of unit mass of water as saturated vapor at pressure of main.

TABLE I. DIAMETER AND RADII OF CONCENTRIC RINGS FOR TEN EQUAL AREAS

Area	Diameter of Outer Edge of Ring	Mean Velocity Point	
		Distance From Center	Distance From Sides of Pipe
1	31.6	11.2	38.8 and 61.2
2	44.7	19.4	30.6 and 69.4
3	54.7	25.0	25.0 and 75.0
4	63.2	29.6	20.4 and 79.6
5	70.7	33.5	16.5 and 83.5
6	77.5	37.1	12.9 and 87.1
7	83.7	40.3	9.7 and 90.3
8	89.4	43.3	6.7 and 93.3
9	94.9	46.1	3.9 and 96.1
10	100.0	48.7	1.3 and 98.7

proximated. The conditions are always adversely affected by bends, connections, off-takes, explosion doors, manholes, etc. If a straight portion of main can be found four to ten times the diameter in length and without valves, off-takes or some other interfering object, the conditions may be assumed to be good for gas measurements.

After this station has been located, it is necessary to determine the inside dimensions of the main in which the flow of gas is to be measured. If the main is horizontal, care should be used in sounding the inside bottom of the main for any deposits of flue dust which may reduce the total cross-sectional area. The area of

*Extracts from a paper read before the Cleveland Section of the Association of Iron and Steel Electrical Engineers, April 11, 1921.

* One atmosphere equals 14.7 lb. per sq. in., 29.92 in. Hg, 33.93 ft. of water at 60 deg., or 407.16 in. of water at 60 deg. One inch of water equals 0.0735 in. of mercury.

In Europe the practice has been somewhat different from that in the United States, as there were early efforts to develop dry cleaners. As a matter of fact, dry cleaners have been operating in Europe for some time and have been mainly objectionable for two reasons: High cost and possible damage to the cleaner.

The cleaners built in Europe were of the bag type and while they cleaned the gas more effectively than any primary cleaner could and even went so far as to prepare the gases for gas engine purposes, the bags, being of a flammable nature, necessarily were subject to destruction whenever the heats put through the cleaners exceeded the safe limits of the material of which the bags were made. The high cost also of installation of this type of cleaners militated very greatly against their adoption and perhaps was the chief reason why such dry cleaners were not installed in this country.

Perhaps a third feature which militated against the use of these dry cleaners was the fact that the sensible heat lost in the cooling of the gas robbed the gas of a great deal of the economies which might be obtained were the sensible heat retained.

Any screen type of cleaner which attempts to filter out particles of dust and fume, even when the filtering medium is not destroyed by the normal heats of the blast-furnace gas, must be sufficiently fine in nature to present a hole smaller than the finest particle of dust and fume going through in order to remove successfully the objectionable solid material in the gas. If the screen is so fine that it will remove the particles of fume, the back pressure will be high and the screen will clog up quickly. If the screen is designed with apertures large enough to prevent any considerable back pressure, the fine particles of fume and dust will go through. The problem, therefore, of screening the fume and dust out of the blast-furnace gas is not a simple one.

It is very evident on further thought that conditions arise when the gas discharging from the furnace top is

very hot and it is impossible to utilize any system of dry cleaning without destroying the cleaning medium. For instance, in the manufacture of ferromanganese, the gases discharging from the furnaces have temperatures running as high as 1,500 deg. F. As steel glows red hot at temperatures of this kind, some necessity arises for cooling the gas to such a point that destruction of the steel does not take place. If it is desirable to cool the gas which is as high as 1,300 deg. F. to a temperature between 400 and 500 deg. so as not to lose the sensible heat which is present in the gas at this lower temperature, care must be taken not to add water for cooling purposes, as the amount of water present when the gas is saturated at 400 deg. F. is so great that it would seriously handicap combustion in the stoves and boilers. A cooler therefore must be of such a type that the heat is transferred from the gas into the water through tubes and not by direct contact.

In actually designing one of these coolers for a ferromanganese furnace the following formulas were used; and it was possible to check the design of this cooler after it went into operation. The results obtained are within 85 per cent of the calculated figures.

Sh = specific heat of gas;

Gw = wt. of gas per hr.;

Gt_1 = temp. of inlet gas;

Gt_2 = temp. of outlet gas;

Wt_1 = temp. of inlet water;

Wt_2 = temp. of outlet water;

C = constant (5);

A = condensing area in sq.ft.

$$A = \frac{Gw \times Sh(Gt_1 - Gt_2)}{[\frac{1}{2}(Gt_1 + Gt_2) - \frac{1}{2}(Wt_1 + Wt_2)] \times C}$$

$$Wt_2 = \frac{Sh \times Ws}{W} \times (Gt_1 - Gt_2) + Wt_1$$

$$\frac{W}{K} = 5 \quad K = Gw.$$

A typical example of calculation per 200 tons pig iron per twenty-four hours is as follows:

200 tons coke per day = 400,000 lb. coke per day
 65 cu.ft. gas per lb.
 26,000,000 cu.ft. gas per day
 1,080,000 cu.ft. gas per hr.
 18,000 cu.ft. gas per min.
 1,080,000 cu.ft. gas per hr.
 Wt. per cu.ft. blast-furnace gas = 0.081 lb.
 Spec. heat blast-furnace gas = 0.24
 Temp. inlet water = 60 deg. F.
 Temp. outlet water = 150 deg. F.
 Temp. inlet gas = 1,200 deg. F.
 Temp. outlet gas = 400 deg. F.
 $1,080,000 \times 0.081 = 88,000$ lb. gas per hr.

$$A = \frac{88,000 \times 0.24 \times (1200 - 400)}{[\frac{1}{2}(1200 + 400) - \frac{1}{2}(60 + 150)] \times 5}$$

$$A = \frac{21,100 \times 800}{(800 - 105) \times 5} = \frac{16,880,000}{695 \times 5}$$

$$A = 4,850 \text{ sq.ft.}$$

1 length 4-in. pipe 30 ft. long has area of 30.14 sq.ft.
 $4850 \div 30.14 = 161$ lengths.

Check:

5 B.t.u.'s transmitted per sq.ft. per hr. per deg. difference in temperature

Then:

4,850 sq.ft. is area.

$$(1,200 + 400) - (150 + 60)$$

2

Then:

B.t.u.'s transmitted per hr. = $4,850 \times 695 \times 5 = 16,900,000$

Now gas given up is 88,000 lb. gas per hr.

Specific heat = 0.24

Difference in temperature, 800

Then B.t.u.'s given up by gas per hr. = $88,000 \times 0.24 \times 800 = 16,850,000$

B.t.u.'s

Water used:

Difference in temp. 90 deg. F.

B.t.u.'s absorbed, 16,900,000 per hr.

16,900,000

$$\frac{16,900,000}{90} = 187,000 \text{ lb. per hr.} = 22,600 \text{ gal. per hr.} = 376.6 \text{ gal. per min.}$$

Chemical Stoneware Manufacture

Production of Chemical Stoneware Involves Ceramic Problems Different From Other Wares for Varying Uses in Chemical Plants—Preparing the Body—Aging the Clay—Fabricating the Pieces—Drying and Burning—Finishing the Burned Ware—Plant Control

By CHESTER H. JONES

POTTERY bodies, common brick, terra cotta, etc., may be likened to cast iron in general qualities of strength and methods of working the raw materials, common stoneware may be compared to malleable iron in physical properties, but chemical stoneware is the *steel* of the ceramic industry. The clay is first weathered, treated and aged, then worked, rolled, pugged and beaten until the resultant product can be handled almost like slabs of leather; it is erected section by section into the shape desired; the piece is tempered in the drying, with time an important factor after the manner of steel, and then it is soaked in the heat of the kiln up to 2,700 deg. F. until complete vitrification is attained throughout the entire body. Thus the finished piece can resist maximum mechanical shocks, temperature changes and acid attack. It may be hammered vigorously without breaking.

As a testimonial to the resistance to temperature variations the first thing that strikes the eye of the visitor at the plant of Maurice A. Knight, at Akron, Ohio, is the apparatus appearing on one of the stacks shown in Fig. 1. Several years ago two 50-gal. acid receivers and two 1½-gal. monkey pumps were mounted in this position. They are subjected to flame from the stack on one side and cold wind and sleet on the other throughout the winter months, yet no deterioration is apparent.

For acid-resistant qualities in general two different bodies are manufactured. One, where hot concentrated fumes like hydrochloric and nitric acids with little condensation must be retained, requires a more porous body to resist expansion and contraction; the other, where corrosive liquids or condensation products are in contact, demands a denser body to obviate possible seepage.

RAW MATERIALS

The clays used in manufacturing chemical stoneware must have high bonding strength, small drying and burning shrinkages and a rather wide range of vitrification. Crushed stoneware scrap is often added as grog to reduce the shrinkage. The Bureau of Mines has issued a valuable bulletin (Technical Paper 233, "The Properties of Some Stoneware Clays," by H. G. Schurecht) describing various tests and properties of these clays as found in the Ohio and Pennsylvania fields.

In general there are seven different clays used at the Maurice A. Knight plant, so blended as to produce as many different stoneware bodies. The manufacture of the different wares requires the study of the chemical engineer co-operating with the ceramist in order that the mix of clays for the body may be varied to meet the conditions of different applications in any acid system. Two clays may have approximately the same

chemical composition but vary in grain size. Tougher bodies are produced by mixing them to get a varying size of silica grain. The chief constituents are alumina, silica and some magnesia with minimum content of iron, lime and alkali salts. Fineness of grain is the most essential physical feature. All clays are carefully analyzed in both the chemical and ceramic laboratories.

The clays arrive by rail, coming principally from the Ohio, Tennessee and New Jersey fields. Some English clays are also used. They vary from plastic ball clay to high-grade plastic fireclay. The raw material is weathered in stock piles for periods ranging from one to six months. The superintendent in charge of purchasing inspects all clay as it is mined, watching the strata closely to be sure the raw product of the pit is uniform.

Dry grinding is employed at this plant in preparing the clay. The whole operation is carried on without the use of blungers or filter presses. A better body for chemical stoneware is obtained by this method, because a considerable amount of salts ordinarily washed out by the blunging and filtering method are retained

FIG. 1. TWO 50-GAL. ACID RECEIVERS AND TWO 1½-GAL. MONKEY PUMPS (ON TOP OF STACK)

to give added toughness and strength as well as longer life to the burned piece. Not only is the clay more easily cut and worked in the plastic stage, but during the firing these ingredients assist in distributing the vitrification through the body to produce a tougher ware.

The ware is often rougher in appearance than is that made by the wet process, but actual breaking tests have shown the burned piece to have greater strength. Toughness and thorough vitrification of body to resist corrosive action are, of course, first requisites of chemical plant apparatus.

The clay mix first enters the two dry pans, one of which is shown in Fig. 2, where it undergoes a long period of grinding. Grog or broken stoneware is ground with the clay for some of the bodies. When the material has reached sufficient fineness it is drawn off to an inclined floor, at the bottom of which are three chaser mills. The fine clay is introduced to these mills, where a certain amount of water is added—just enough to secure a workable product. Grog is used only in batches for making larger ware.

From two and one-half to four hours is required for this operation. The chaser mill resembles the dry pan in general appearance except that the wheels have only

FIG. 2. DRY PANS

a 3-in. face and the pan remains stationary while the horizontal axle carrying the wheels is revolved about a vertical central shaft. At the same time this axle is being turned on a pivot normal to its axis the wheels sliding upon it are "chased" back and forth from the center to the outer edge of the pan, thus grinding the wet clay over all parts of the bottom.

The chaser is an old piece of equipment in the clay industry and has been largely superseded by the wet pan and other processes. Its output is limited both because of size of batch and because of speed of operation. The quality of product turned out is of the finest

and toughest texture, mainly because the method tempers as well as grinds the clay.

When each chaser batch is finished as determined by an operator who becomes expert on the "feel" as well as the formula, it is transferred to the concrete aging pits, where it remains for varying periods, the longest being about six months. During this time it is covered with sacking or burlap, which is moistened each day.

FIG. 3. AUGER MACHINE

The practical effect of aging this clay is to increase its plasticity and toughness. It has a "rubbery" appearance and feel.

Recent research into the reason for aging clay and the phenomena involved has indicated that during the aging period there is a growth of green filamentous algæ as examined under the microscope. This growing is accompanied by the evolution of CO and CO₂. The next point is to determine why the presence of this algal growth increases the plasticity, and the work of H. Spurrier and others will be awaited with interest.

When the clay is removed from the aging pits the edges and surfaces are trimmed off. These trimmings, together with clay trimmings from subsequent forming processes are used in making chemical brick. Thus only the very tough dense product from the inner part of each pile is used in forming other chemical ware. Two-ton Bonnot repress brick machines with others are located on the same floor as the aging pits. The clay for various shapes and vessels is transported on shelf elevators to the upper floors, where it enters the structural departments.

Next in importance to the scientific selection of raw materials and careful preparation of the plastic, tough clay under technical control come the design and erection of the piece to give the best service in the chemical plant. This is truly a function of chemical engineering—namely, to evolve the most suitable mechanical device that will best handle the certain phase of the chemical process. The potter is guided by the engineer to devote his skill and training to chemical plant design.

The technique of stoneware manufacture requires considerable mechanical care. Shrinkage in drying and burning must be taken into consideration in the original dimensions of the wet piece. This varies from 8 to 12 per cent of the volume, with an average of 10 per cent, in the drying and firing shrinkage. Accuracy of measurement is very necessary since many of the parts must fit together when erected in place.

The section devoted to the manufacture of stoneware pipe employs a J. D. Fate auger machine shown in Fig. 3. The sacking in the right foreground covers the operating stock of clay to prevent surface drying.

"The 'Why' of Aging Clay," *J. Am. Cer. Soc.*, vol. 4, No. 2.

FIG. 4. MANIFOLD FOR NITRIC ACID

All working piles, as well as newly formed ware about the plant, are kept thus protected. In the case of the latter protection is necessary to prevent too rapid drying and surface cracking.

The clay is thrown into the chamber of this machine and pipe is extruded through suitable dies on the left end, the clay being forced out by a slowly revolving screw. This method produces pipes free from laminations, such as may occur in sewer pipe presses. Fig. 4 shows some special nitric acid manifolds. The main length is formed in the auger machine, while the branches are made by hand and on the potter's wheel or jigger. Other small pieces are turned on ordinary machine lathes. The whole is assembled by careful hand work. Chamotte pipes do not require a tight vitreous body, because they convey only hot gases with no condensation. Fireclay would disintegrate if used for this purpose. This open, porous body is of course not used where much liquid is present.

Another machine used in making pipe sections is the sewer pipe press operated by steam pressure. It will produce pieces from 2 in. to 36 in. in diameter, but is used only for the smaller bores, where the possibility of laminations is minimized. The converging pressure during the molding of the smaller diameter pieces works the clay to prevent such laminations. Larger bore pipe such as tower sections are all hand built the same as receivers and jars.

Large pieces of chemical stoneware are made entirely by hand. Plaster of paris molds are first built in take-down sections. One of these assembled molds appears on the extreme left of Fig. 5. The pieces in the foreground are finished filter bottoms resting in the bottom mold with the side sections of the mold removed.

The clay for this construction is battled and rolled out into sheets near the required thickness and of such dimensions as the modeler can pick up from the table and transfer to the mold. These sheets are easily handled, being quite tough and flexible. The modeler

FIG. 5. FINISHED FILTER BOTTOMS

slaps them into the mold and proceeds to work them into place, taking special care to see that the line of juncture with adjacent pieces is entirely eliminated by working the plastic material to a firm weld. A joint thus made is said to be stronger and less apt to break than other parts of the piece. The whole operation reminds the spectator of movements carried on in the welding of steel tanks.

When the work is complete and the clay has become one piece, the sides of the mold are immediately removed, the bottom of the mold being left for a support until the air drying is completed. Wet cloths are thrown over the top, as seen in the left of Fig. 6, to prevent premature drying. Finally these are removed, as seen on the right in the same picture, and the heaviest piece may be lifted by the rim in transferring to the driers—a fact which roughly demonstrates the bonding strength of the clay.

Further question of shape may be noted in these large pieces. Examination of the foremost piece in Fig. 5 will show that the vertical outline is not straight, but curves outward toward the bottom. This is necessary, because the moisture aided by capillary action settles to the bottom during drying and would warp the piece unless provided for in the first place. This ware

FIG. 6. LARGE PIECES OF CHEMICAL STONEWARE

when burned will have the perfectly straight edge as intended by the designer. Like irregularities must be worked in throughout the fabrication of all sorts of shapes. In the tank department units up to 500-gal. capacity can be made, but it is recommended that sizes be limited in general to 200-gal. capacity so that in case of accidental breakage less solution will be lost.

One of the large-quantity products of the Knight company is the etching machine which is sold to engravers, photographers and printing establishments. Several of these are shown ready for the drying room in Fig. 7. The four holes in the side of the box permit the introduction of four revolving paddle wheels, one of which is seen lying across the top of the box, with others drying on the floor in the immediate foreground. The piece of clay pipe lying across the top of each box is a temporary support to hold the walls in place during drying and burning.

Thin sections of dense clay are required in the manufacture of this ware and other containers and condensers for hydrochloric and nitric acids. Here the temperature changes are not great, but liquid must not seep through the pores. Battery jars and electrolytic cells likewise require a dense body, but the sides are built heavier to support the electrodes. The pieces shown in Fig. 8 are parts for the electrolytic cell units in the process of air drying.

FIG. 7. ETCHING MACHINES

The finished piece shown in the foreground of Fig. 9 is a 2-in. bore 100 ft. condenser coil for nitric acid, one which always attracts attention to the apparent intricacy of the modeler's work. Its manufacture is, however, quite simple. The support is first built up and then the necessary length of pipe is taken moist as it comes from the auger machine and wound into place by hand, care being taken to allow for necessary shrinkage in drying and burning. A piece of asbestos sheet is inserted between each lug and the section of pipe which rests upon it. This prevents the pipe from burning to the lug in the kiln and permits the entire coil in contracting to slip over the lugs. When the piece is finished, the coil may contract and expand independently of the movement of the supports. The asbestos pieces are changed to a ceramic material by

FIG. 8. PARTS FOR ELECTROLYTIC CELLS IN PROCESS OF DRYING

the heat and resemble burned clay. They remain in place to give an even support to the coil.

The development has just been completed of a porous chemical stoneware acid carboy stopper. It is shaped like a button head rivet with slightly tapered shank and with crossed groove in the head to receive the wires for binding over the mouth of the carboy. The smooth surface on the under side of the head fits against the rim of the mouth and a rubber or asbestos washer is inserted between.

The clay body is burned porous so that gas will leak through to the outer air but so that liquid will not permeate the pores to any extent. The release of gas prevents the blowing out of stoppers. The importance of this feature is readily recognized by shippers of concentrated nitric acid, who are familiar with fires started in cars and warehouses during warm weather

by the carboys breaking and acid igniting the packing and crating. These stoppers are made on a press which machines the shank and under portion of the head and molds the head in the same operation. It is manufactured by the Baird Machine & Manufacturing Co. of Detroit and produces fifteen stoppers per minute.

Stoneware cocks and faucets are made from clay stock specially selected from the center of the aging pits. The shapes are worked up in the jigger, a potter's wheel with mold top, and are worked by hand to give the desired key or bowl. The key and bowl of such faucet travel as mates through the entire process. They are identified by numbers stamped in the plastic clay, which differs from common practice of stamping a lead plug inserted after burning.

In making faucets, pipe, etc., the threads are cut in

FIG. 9. CONDENSER COILS FOR NITRIC ACID

the wet clay on a machine tool lathe, which insures clean, fine threads after the ware is burned. Comparison with molded threads at once shows the value of this operation. The lathe used is a standard metal-cutting machine made by the Strong, Carlisle & Hammond Co.

After the two parts of a faucet have been through the kiln, the key is mounted, tapered end up, in a jigger and revolved while the operator holding the bowl grinds it to a perfect fit. Wet carborundum dust is applied as the only abrasive which will cut the vitrified material. Fig. 10 shows faucet parts in the grinding room. In the manufacture of stoneware pumps the piston is ground to the cylinder in exactly the same manner. Perfect hollow spheres used for valves in automatic acid lifts are produced by grinding. Nitrating kettles and autoclaves with stirrers having fitted stuffing boxes all made of stoneware may be operated under gas pressure of 40 lb. and upward. All such parts may be lubricated with ordinary oils or greases.

FIG. 10. FAUCET PARTS IN THE GRINDING ROOM

FIG. 11. METHODS OF LOADING WARE IN THE KILN

With the clay worked to so many shapes and sections in the same piece, the process of proper drying becomes most important. As previously mentioned, all possible skill is used in the fabrication to preserve the body from warping with the 10 per cent shrinkage occurring in drying and firing. The removal of moisture must be very slow at first to prevent surface cracking and produce tough body.

The finished pieces are first allowed to set in the air of the molding rooms under wet sacking covers as mentioned and shown in the preceding photographs. The period in the room air drying just before the clay becomes set is the critical point where the wet sack covering is most important.

The actual structure of a mass of clay to be dried is made up of grains of material, each grain being surrounded by a pool of water, which gives cohesion to retain the shape. During the drying process the capillaries in the mass become smaller. The water on the exposed surface evaporates and the water inside flows to the surface through the capillaries. Shrinkage is caused by the removal of these pools of water and by the particles coming in closer contact. Aside from the capillaries, there are still pores between the particles.

In this first part of the drying process carried on in the air of the room for periods varying from one to eight weeks the shrinkage is proportional to the water removed due to this contraction of capillaries. The subsequent removal of the water in the hot driers is not accompanied by much shrinkage. In surface evaporation the safe rate of drying must not be greater than the rate at which the water comes from the inside of the mass through the capillaries; otherwise surface strains are set up, causing cracks, because the plastic interior is non-compressible.

After the ware has undergone the initial set, it is removed to the hot drier, which consists essentially of

a large room with shelves located over a grated wooden floor beneath which steam pipes are laid. Here it is allowed to remain from three days to two weeks—that is, until all but the hygroscopic water is driven off, leaving the ware ready for the kiln.

The burning equipment of this plant consists of six 30-ft. periodic down-draft kilns, each one connected with individual flue of a double stack. High-grade Pittsburgh coal is employed for fuel.

Fig. 11 shows ware stacked in the kiln ready for burning. Chemical brick or tile is piled up from the floor for a height of about 3 ft. to form a checkerwork for an equal distribution of the draft over the whole kiln. This also lifts the finer structure pieces to the best heat zone of the kiln. Chemical brick is then a sort of byproduct of the molded ware, not only because the trimmings of the aging pit and modeling room are used as raw material but also in regard to this need of a distribution bottom in the kiln setting. The resulting brick are therefore made from much better material and burned more cheaply than could be accomplished in the case of manufacturing the one product.

No cones are used in recording the temperatures during burning. An indicating Price temperature recorder is located in the foreman's office, and a recording instrument of the same type is placed in the general manager's office, as shown in Fig. 12. The multiple switch in the upper left hand corner is used for switching the instrument to connect with any kiln. The recorder marks the sheet by perforating at intervals with an electric spark. The electricity is furnished from dry cells contained in the case to the right of the instrument.

The burning time varies from five to eight days, depending on the size and thickness of the ware. The first operation, which consists of water smoking, is carried on for two or three days at a temperature up to

FIG. 12. KILN TEMPERATURE RECORDS

FIG. 13. CLOSE-UP VIEWS OF FINISHED WARE
IN THE KILN

300 deg. F. While the material from the hot driers is apparently dry, it still contains a large quantity of hygroscopic water as well as the water chemically combined with the clay. During this period a large amount of white steam issues from the stack. The driving off must be carried on slowly or the water will be too quickly converted to steam and the clay body be damaged. This is particularly true in the case of dense stoneware clays where the pores are exceedingly small, permitting only a slow passage of water vapor from the interior of the body.

When this period is completed as determined by moisture tests of the stack gases, the drafts are opened and the firing increased up to 1,000 deg. F. This step is to drive off the water of crystallization or chemical combination, which occurs quite rapidly at this temperature. The temperature rises quite slowly at this time, however, because a large quantity of the heat is absorbed in breaking off the water. At the same time any carbonates present are broken up to form oxides and CO_2 , which absorbs additional heat. The end of this operation may be determined by weighing the test-pieces until loss of weight is no longer evident.

During the latter part of this period the oxidation of any materials like ferrous oxide, carbon, sulphur, etc., that may be present takes place. Since chemical stoneware clays are selected nearly free from such elements, the vitrification stage is almost immediately entered upon. It requires about two days' time to raise from the water smoking stage, about 300 deg. F., to the vitrification or maximum temperature, 2,600 to 2,700 deg. F. Vitrification really begins at the lower temperature, but does not become apparent to the observer until the higher temperatures are reached. The high soaking temperature runs about twenty-four hours from 2,000 deg. F. up to the maximum, 2,700 deg. F.

It is here that the size of grain of the different clays, as mentioned at the beginning of this article, exerts the most profound influence in governing the kind and amount of body fluxing. The fineness of grain insures more ready assimilation of every particle to form a homogeneous body completely vitrified throughout. It makes for a tough, strong body impervious to corrosive attacks in the finished piece. True in case of the heavy, thick sectioned pieces where grog is used to give firm skeleton to hold this mass to shape when in the hot colloidal condition, the bits of grog do not melt down. It will be recalled, however, that this grog was ground from previously burned stoneware in the first place and is therefore tough and impervious to acid.

During the high soaking period a few pounds of com-

mon salt is thrown into each firebox to give a glaze to the ware. This is in no way for the purpose of adding to the acid-resisting properties, but is simply to give a finished appearance. Finally, the fires are permitted to die down and the kilns to cool for three or four days before opening.

Fig. 13 is a close-up view of the interior of a kiln, with the finished ware in place. Note that the shapes are stacked on the brick checkerwork as mentioned above. The shapes vary in size from carboy stoppers to large receivers. No saggars or containers are used. In some cases bats separate the larger pieces to prevent fusion of the glaze. The maximum life of kilns burning this class of ware is about ten years, but arches, bag walls and fireboxes must be repaired every six months. It will be seen in comparing this picture of the burned ware with that of the unburned ware in Fig. 11 that they have become darker in appearance. They are in fact changed in color to a brownish red.

The ware is finally sent from kiln to finishing plant, where it is ground to accurate surfaces on revolving grinding tables using carborundum as an abrasive. All vesse's undergo tests for ability to retain liquids.

APPARATUS MANUFACTURED

While some standard pieces are turned out, it is just as cheap to produce the desired ware from customer's blueprint. It is easily recognized from the foregoing paragraphs that the operations of manufacture require hand skill of individual craftsmen in every stage, which of course is as readily applied on special pieces as on the standard. Order number and blueprint number are stamped and burned in every article.

The field of use for chemical stoneware embraces acid manufacturers, acid users, etching plants, printing plants, photographic houses, electrolytic plants, paper mil's, steel galvanizing and pickling plants, soap manufacturers, fertilizer producers, ink, dye, paint, insecticide and pharmaceutical manufacturers. Reclaiming plants for rubber and bleaching houses use a considerable variety of stoneware apparatus. Producers of organic chemicals of all sorts and even laboratories in the industries employ some small chemical stoneware utensils, such as sinks, waste pipe lines, burner guards, funnels, pitchers, filters and jars.

An acid-proof cement, high in silica and free from soluble salts, is ground in pebble mills to pass 80-mesh screen and bagged for the market. It may be used in chemical plants in the construction of masonry work which will come in contact with hot or cold, strong or weak and liquid or gaseous acids. This powder is mixed on the job with enough 30 to 40 deg. Bé. silicate of soda solution to make a uniform stiff mortar. About forty parts by weight of the solution is required for one hundred parts of cement powder. The cement will harden at ordinary temperature with free access of air.

ORGANIZATION

Every workman in the plant is his own foreman, an ideal condition for the development of true craftsmanship. There is no piece work whatever. The entire organization is headed by one general manager and his assistant. The whole forms a body of contented workmen functioning through personal contact with one head.

The writer is indebted to Maurice A. Knight for courtesy and information furnished in the preparation of this article.

Synopsis of Recent Chemical & Metallurgical Literature

Measurement of Surface Tension.—A. W. Fahrenwald, ore dressing engineer of the Bureau of Mines, has devised a simple instrument for measuring the surface tension of liquids by measuring the pull required to rupture a film of known width. A full description is given in the August 13, 1921, issue of *Mining and Scientific Press*. As shown in the accompanying illustration a 2½-in. cork *C* is pivoted on knife edges *D* and carries a pointer *E* indicating equal horizontal movements of the center of gravity of the pointer.

Over the cork is swung a No. 50 cotton thread, counterweighing a silver or aluminum bar *K* whose horizontal member (6 cm. long) is sharpened into a knife edge below. Small horns at the end are to prevent the film pulling away at the ends.

If the watch glass *J* containing the liquid to be measured is raised by means of band-wheel *F* until the liquid engages the knife edge, and then slowly lowered, a plane film will

DEVICE FOR MEASURING SURFACE TENSION

be drawn out. Tension existing in this film rotates the indicator. Two characteristic points will be observed. The first breaking in water, for instance, will swing the pointer up to about the 80 dyne graduation, as the upper surface of the horizontal bar comes through the surface film. Then as the liquid is lowered further, a film will be drawn from the lower edge, and the pointer will drop to a constant reading, representing the true tension.

The method is independent of the wetting of the bar by the liquid to be tested. It measures the force required to break a film of considerable length, and the experiment can be done in a few seconds.

The conversion formula is

$$S = \frac{981W}{2L}$$

where *S* is the surface tension in degrees per centimeter; *W* is the weight in grams producing the same deflection in the pointer; 981 dynes equals one gram and *L* is the width of film. The influence of the horns may be estimated by drawing a film from them without touching the knife edge to the surface.

Using this method, the surface tension of water at 20 deg. C. figures 92.85 dynes per cm., a figure in close agreement with the most accurate figures published.

Critical Review of Wet Process for Manufacture of Portland Cement.—The question whether the wet or dry process is best for the manufacture of portland cement from hard, dry raw materials is still an open one in this country. A critical comparison of the two processes was made by Richard K. Meade in the Cement Mill Section of *Concrete* for May, 1921.

The author first considers in detail the following advantages claimed for the wet process:

(1) That a better and more uniform cement can be manufactured by the wet process than by the dry, owing to the fact that a more satisfactory mixture of the raw material can be made, a more constant composition can be maintained, and the particles of material can be brought into more intimate contact.

(2) That wet materials can be more easily ground than dry, the operation requiring less power and the repair item being less. That the output of the mills is also greater, which decreases the investment in the plant and consequently lessens interest, depreciation, etc.

(3) That the raw materials do not need to be dried, which effects a saving of the fuel and equipment necessary for this, with the labor, power, repairs, overhead, depreciation on the latter, etc.

(4) That the clinker of the wet process is more easily ground than that of the dry.

(5) That wet materials are more easily handled than dry.

(6) That there is less dust connected with the wet process than with the dry.

Turning to the advantages of the dry process, the author states that these lie almost entirely in the fact that less coal is employed for burning. Data on the fuel requirements of the two processes are tabulated for eight plants with dry process rotary kiln (three plants using oil and five powered coal as fuel) and for six plants with wet process rotary kilns (three using gas and three pulverized coal). The average heat requirements per bbl. of cement were found to be 1,219,000 B.t.u. for the dry and 1,696,317 B.t.u. for the wet, a difference of 477,317 B.t.u. Since good Pennsylvania and West Virginia gas slack has a heating value of approximately 14,000 B.t.u. per lb., this difference is equivalent to 34 lb. of coal.

It has long been recognized that the rotary kiln is wasteful of heat and that its actual efficiency probably does not amount to more than 25 per cent. Most advocates of the wet process have held that the other 75 per cent could be very

TABLE I. HEAT LOSSES OF THE ROTARY KILN

	Per Cent
Carried off by the hot clinker.....	13
Carried off by the stack gases.....	40
Utilized to decompose carbonates.....	27
Lost by radiation, etc.....	20
Total	100

readily put to useful work in driving off the water from the wet slurry. A review of the heat balance of the rotary kiln, however, shows that this is by no means the case. Table I may be said to summarize fairly the situation in a dry process plant.

Even a glance at Table I will show that the only portion of the loss which can be utilized in evaporating water is that represented in the waste gases, or, in other words, 40 per cent of the total heat of the fuel and not 75 per cent. It would not be possible, however, to recover even all of the 40 per cent carried off by the waste gases because some

heat would have to remain in the gases to produce draft, unless fans were used.

The percentage of water in the slurry of the wet process varies considerably. As a general rule, however, at least $\frac{1}{3}$ of the slurry is water, or about 300 lb. per bbl. of cement.

To evaporate 300 lb. of water from an initial temperature of 60 deg. C. would require 336,720 B.t.u. In the dry process, assuming 87 lb. of coal per bbl. of cement and 10 per cent excess air, there would be about 1,233 lb. of waste gases leaving the kiln at 1,600 deg. F. and containing 545,552 B.t.u. If the gases were to leave the kiln at 400 deg. F.—a temperature sufficient to produce the necessary draft—they would contain only 119,048 B.t.u., or 426,504 B.t.u. less than at 1,600 deg. F. This difference is more than sufficient to evaporate the 300 lb. of water and heat the vapor to 400 deg. F. ($336,720 \text{ B.t.u.} + 54,000 \text{ B.t.u.} = 390,720 \text{ B.t.u.}$). Thus it is seen that 87 lb. of coal would produce a barrel of cement by the wet process provided that the waste gases left the kiln at 400 deg. F. In practice, however, the temperature of the waste gases from a wet process kiln is from 800 to 1,100 deg. F. This accounts for the greater fuel consumption.

By the use of waste heat boilers a final temperature of 400 deg. F. may be reached. In the dry process, as indicated above, the 1,233 lb. of gases at 1,600 deg. F. containing 545,552 B.t.u. can give up 390,720 B.t.u. in cooling to 400 deg. F. This is equivalent to 11.6 boiler hp., or 401 lb. of steam at and from 212 deg. F. If delivered to a modern turbine plant (which is usually rated at 17.5 lb. of steam at 200 lb. pressure and 100 deg. superheat per kw.-hr.) the power output would be 20 kw.-hr. Approximately 10.5 boiler hp. is being actually recovered per bbl. of clinker in many plants. In some instances this steam is being used in old equipment, but where employed in modern turbine installations, an output of 16 to 18 kw.-hr. is being obtained, or enough to operate the entire plant, including both clinker and raw mills.

It is, of course, possible to install waste heat boilers with wet process kilns, but in this case 121 lb. of coal gives about 2,000 lb. of gases at about 900 deg. F. containing approximately 500,000 B.t.u. While the total heat in the waste gases is about the same as in the dry process, more coal has been required and the greater volume of gas, coupled with its lower temperature, makes the amount of recoverable heat much less than in the dry process.

In conclusion the author points out that the possible saving of the wet process in grinding and drying is much more than offset by the saving of the dry process in fuel, while the advantages claimed for the wet process as to lack of dust and better quality of product are not borne out by either facts or theories.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Decolorizing Carbon.—A decolorizing carbon is prepared from the waste filter-press residues from the refining of edible oils, such as cottonseed oil or shea-nut oil, by heating them in a reverberatory or similar furnace at a temperature just above the flash-point of the oil they contain, and with restricted admission of air. The product, which is a porous carbonaceous mass, is cooled out of contact with the air, washed with dilute acid to neutralize any alkaline salts formed by the incineration of contaminating soaps, and finally pressed into cakes and dried. Lamp-black is collected as a combustion product in the flue of the furnaces. (Br. Pat. 162,117; De Bruyn, Ltd., and C. Revis, both in London; June 15, 1921.)

Electrolytic Production of Boron.—Boron is produced by electrolysis of fused boric acid made conductive by the ad-

dition of a suitable substance such as borax. Both electrodes may be metallic or the anode may be of retort carbon. Carbon monoxide and carbon dioxide formed in the latter case assist in the operation. The process is carried out in a closed vessel having an outlet pipe for gases. The vessel may be of insulating material or of metal and in the latter case forms the cathode. The cables pass through the wall of the vessel or through the cover. Boron so produced may be used as a reducing agent in metallurgy. (Br. Pat. 162,252, not yet accepted; C. Constant and V. Raisin, both of Paris; June 15, 1921.)

Electric Furnace.—In an electric furnace pairs or groups of electrodes of uniform thickness are brought into contact and are maintained in contact by hand or by automatic devices. Means are provided to permit the substitution of new electrodes when the old ones are nearly consumed. Meters are preferably used with each pair of electrodes to facilitate the control of the voltage. A high current density is used so that heat generated through the resistance of the electrodes themselves contributes to the general heating effect. The arrangement is stated to be applicable to rotary furnaces consisting of a horizontal cylinder of large diameter provided with lateral cylindrical or conical drum-shaped extensions of a less diameter. The electrodes are introduced through the walls of the cylinder around the extensions which may be used for charging. (Br. Pat. 162,285; not yet accepted. A. H. Pehrson, Stockholm; June 22, 1921.)

Catalytic Hydrogenation of Fats.—A catalyst for use in the hydrogenation of fats or oils consists of nickel wool which has been activated by the action of an acid such as nitric acid upon its surface followed by conversion of the layer of nickel salt to oxide and reduction in hydrogen. The reaction chamber is packed with the activated nickel wool and the oil and hydrogen passed through in counter-current. After use the catalyst is regenerated by first removing nickel soaps by washing with the hot oil, then removing the oil by solvents and finally heating in hydrogen. According to the provisional specification, the nickel wool may be activated by alternate oxidation and reduction, the catalyst may be electrically heated, and a number of reaction vessels may be arranged in series. (Br. Pat. 162,370. E. R. Bolton, London; June 22, 1921. See also Br. Pat. 162,382.)

Cleaning Electrolytically Iron or Iron Alloy Surfaces.—Iron or iron alloy surfaces which are to receive a deposit are electrolytically cleaned in an acid solution of a copper salt. A suitable solution contains 10 to 12 per cent of sulphuric acid and 5 to 10 per cent of copper sulphate. If the surface is very dirty, it is connected first as cathode and then as anode; otherwise it may be employed as anode only. A current density of 150 to 500 amp. per sq.ft. and a pressure of 8 to 20 volts may be employed. The other electrode may be of lead and may form the lining of the vat. Temperatures from that of the atmosphere up to 120 deg. F. are allowable. Grease is removed before the above treatment. After the electrolytic cleaning the surfaces may be directly coated with iron, nickel or cobalt. Worn surface of machinery may be refaced by this process, the deposited iron being case-hardened if desired. (Br. Pat. 162,391. R. J. Fletcher, London; June 22, 1921.)

Process for Desulphurizing Iron and Steel.—In a process for desulphurizing iron and steel the iron bath is freed from phosphorus, manganese, etc., and the slag layer is removed and replaced by a new thick layer of highly basic slag into which specially prepared carbon, having approximately the same specific gravity of the slag, is immersed for the purpose of converting in a neutral atmosphere the sulphur into calcium sulphide and at the same time remove the last traces of oxygen in the form of carbon monoxide. The carbon is prepared by mixing finely ground coke with tar and forming the mixture under great pressure into blocks provided in some cases with perforations. When required, the slag bath is regenerated after the molten iron has been removed, by passing a current of air over or through the slag. (Br. Pat. 162,618; not yet accepted. Koppers, Essen, Germany; June 22, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Embargo Extension Bill Passed by House

The Longworth bill extending the embargo on dyes and chemicals was passed by the House on Aug. 11 by a vote of 186 to 91. The action was taken promptly after the receipt of the following letter from President Harding to Representative Longworth:

I have your note calling my attention to the fact that the bill extending the provisions of the emergency tariff act relating to the protection of the American dye and chemical industry is to be before the House on the morrow. I am sure that the Secretary of the Treasury has already called the attention of your committee to the extreme desirability of extending this protective provision. Surely, we would be both unmindful and unjust if we failed in a suitable protection of this industry until the new and complete tariff revision act is made effective.

In recommending the passage of the bill, the committee submitted the following:

Under the present emergency tariff law the provision relating to the control by the Government over importations of dyes and chemicals expires three months after the date of the approval of the act—namely, on Aug. 27, 1921.

It now seems evident that the permanent tariff law will not be enacted until some months thereafter. Therefore, during the time elapsing between Aug. 27 and the final enactment of the tariff law the rates of duty of the Underwood law would apply to all importations of dyes and chemicals. These rates of duty are admittedly insufficient to prevent importations of enormous quantities of these chemicals to an extent sufficient to seriously menace or even destroy the American coal-tar and synthetic chemical industry.

Dye Embargo Argued Extensively at Senate Hearings

The dye embargo still hangs in the balance before the Senate Committee on Finance at the time of this writing. The hearings were prolonged unexpectedly. The committee had planned to terminate those on the dye embargo and on the American valuations a full week sooner than it did. The importance of this concession can be realized only by those having first-hand knowledge of the pressure under which the Finance Committee is working as a result of the pending tariff and taxation legislation. The extension of the hearings signifies that the Finance Committee attaches the greatest importance to the proposal that more than duties are required to protect the dye industry. Owing to the important bearing that these two matters will have on the action which the committee will take on the remainder of the tariff bill, an early decision is to be reached in the matter of the dye embargo and the type of valuation which is to be used.

LETTER FROM THE SECRETARY OF WAR

As a result of the extension of the hearings a very full presentation has been made of the entire dye proposition. One of the most important points emphasized in favor of the embargo was the relation it has to the national defense. The Secretary of War, who for many years was a member of the Senate and whose opinion has great weight with that body, wrote a forceful letter to Senator Penrose, the chairman of the Finance Committee, in which he urges the embargo in the interest of national defense. His letter, in part, is as follows:

One of the most startling discoveries of the World War was the fact that the United States could mobilize, train and equip with clothing three or four million men far quicker than it could supply the cannon, the rifles, and the ammunition for them. Notwithstanding that from 1914 to 1917 our great steel industries and our

rapidly developing chemical industries had been working feverishly to increase their facilities to supply ammunition and guns to the Allies, it was more than a year after we entered the war before those industries were able to supply ammunition, war gases, guns and rifles to meet American needs. Even then our chemical industries were so undeveloped in 1917 that it was necessary for the Government to build tremendous high explosive plants, as at Nitro, W. Va., and practically all poisonous gas plants for supplying gases and smoke materials to the United States Army.

The use of high explosives and war gases will unquestionably be far greater in any future struggle than in the World War. Inasmuch as the coal-tar industry, which is the base of all dyes, is also the base of all high explosives and most of our war gases, it is of the most vital importance to preparedness that the dye industry be developed to the fullest possible extent in this country. It is felt that this danger is so great that I urge the enactment of the embargo feature of the Fordney tariff bill as submitted by the Ways and Means Committee of the House as the only way to prevent crushing our chemical market by German competition.

CONSIDERATIONS URGED BY DYE MANUFACTURERS

Joseph H. Choate, representing the American Dyes Institute, was examined at length by the committee. His testimony necessarily covered the same ground many times, due to questions asked by members of the committee duplicating questions which had been asked previously by another member. Among the considerations which Mr. Choate urged as proper in governing the final decision of the committee are these:

First. Now, and now only, can we secure a real dye industry. While the Germans retain their present advantages, and the power and necessities of the great trust compel that attack which we deem inevitable, their commercial warfare will instantly kill our industry unless whatever protection is provided is truly efficient. Once killed, it could never be revived. If it be not saved now and promoted as well as protected, American capital will never again go into it, and a world monopoly will be handed back to Germany for all time.

Second. Since it is certain that there will never be another opportunity to provide the United States with a real dye industry, it is the duty of Congress, if it believes such an industry to be essential, to take no chances. The stake is too great for any gamble; and to adopt any method of protection with doubt as to its efficacy is to gamble with an interest vital to the whole country. According to the overwhelming weight of the testimony, we submit, no tariff practically enactable can furnish the protection needed.

Third. Only the complete protection and efficient promotion of our dye industry can insure the safety of the textile makers themselves. As long as the German industry is in one single hand, and that hand at the disposal of its government, it can and will be used to further any national ambition.

Fourth. If capital is to be attracted into and kept in the dye industry the necessary special protection must be assured for a period long enough to permit the development of most of the missing dyes. The testimony leaves no real doubt that three years is wholly inadequate.

CHOATE ANSWERS ARGUMENTS OF METZ

By far the most formidable witness who appeared in opposition to the embargo was Herman A. Metz of New York. Realizing that, Mr. Choate took pains to answer his arguments in detail. Among the things which Mr. Choate told the committee in that connection is the following:

Mr. Metz gave no figures anywhere as to the manufacture of dyes which would support his contention that the industry can survive in this country when protected only by an ordinary tariff. He laid great stress, however, upon the manufacture of salvarsan. As to that, I would like to have the committee remember that

he told you that salvarsan was a product in making which no byproducts were produced. That sort of manufacture is relatively simple when compared with the enormous complications of dye making, involving a great many byproducts, which are really the key to the situation.

It is true that he did reduce the price from \$2.25 to 27c. That shows the remarkable effect of the competition to which he was subjected, and it also shows that the pre-war price in our market of a commodity on which the Germans had a monopoly was probably excessive.

Mr. Metz says that dye plants are no more fitted for the manufacture of explosives than are breweries. Notice that he does not say that they are not fitted for making poison gas. He does not attempt to contradict General Fries on that. He says the only dye plants good for war purposes are those which include nitrating plants. All considerable dye plants have nitrating plants, and a very large proportion of the dyes that are made require nitrating sooner or later. He says there are only eight plants in the country that nitrate. In that connection permit me to say that one of the witnesses to be heard later will show the existence of at least thirteen plants which nitrate.

Mr. Metz says, "I am not afraid of the Germans." Why should he be? Just before that he had said, "I am a representative of the great Hoechst concern."

DEFENSE OF WAR TRADE BOARD

Vigorous denial that the War Trade Board has shown favoritism in issuing import trade permits was made by Henry B. Thompson, chairman of the advisory committee, War Trade Board. It had been alleged by an earlier witness that he had applied for a permit for a certain product from Germany, but was turned down with the explanation that it could be had in this country.

Mr. Thompson told the committee that he was a manufacturer and that he dyed cotton goods and certain lines of the textile industry. He said that in all his experiences with American dyes they answered his purposes splendidly and that he expected to continue to use them, despite any importation of foreign colors.

"Give the American manufacturer an opportunity to produce what is wanted," Mr. Thompson said. "The only thing we lack today, I must admit, are certain vat colors, but we can get along without them. The industry in America has made wonderful progress, and as soon as we are able to get together an efficient staff of organic chemists we shall gladly meet competition. The cry for German dyes has caused no one any serious suffering. We can match any shade—that is, we can match it in a way that will be acceptable to the trade."

HOSIERY MANUFACTURERS OPPOSE EMBARGO

George Demming, representing the National Association of Hosiery and Underwear Manufacturers, declared that Henry B. Thompson, who appeared as a representative of the advisory committee of the State Department in matters pertaining to dye imports, made the following assertion to the Finance Committee nearly two years ago:

"It is true we do not make the vat dyes in this country, and it is true that the mill men should have them. They must have them. But we expect to have them in six months or a year."

Mr. Demming cited that language in an effort to discredit Mr. Thompson's statement that the embargo could be dispensed with after three or four years. Senator Smoot suggested that it would take fifty years of embargoes to give the dye makers the encouragement that they desire.

Mr. Demming, continuing along the same line, said: "Two years ago Nicholas Longworth, one of the principal proponents of this present proposed legislation, got up on the floor of the House, and in the most emphatic and deliberate way, in a prepared speech, said that all that the American domestic dye manufacturer needed was two years of an embargo, and that then they could turn out all these dyes and take care of ourselves. I remember hearing that speech. We have had that embargo for over two years, and now they want three years more of it."

At another point in his testimony Mr. Demming said: "The licensing law in England is not only a very different law from that proposed here, as I will show to you, but it

is also for the protection of a company over there in which the government participates and which the government controls. Now that is very different from the embargo and licensing proposed here for the benefit of private individuals to roll up any profit for themselves that they can under the umbrella of that embargo and licensing."

CHEMICAL WARFARE HEAD TESTIFIES

The Finance Committee paid particularly close attention to the testimony of General Fries, head of the Chemical Warfare Service. A brief extract from General Fries' testimony follows:

We have felt that the embargo was a success during the war in building up this industry from, say, 7 plants to 82, and that if it had done that during this time, the embargo, continued for some time, would eventually develop our industry to the point where we would be making practically all the dyes that Germany is making and we would be utilizing all of the coal-tar products. In other words, before they do that they have got to change over many beehive coke ovens to those that will save the coal tar.

Looking at it from the result before the war, when we had a duty on dyes and when we had made practically no progress, and looking at the progress we made under the six- or seven-year embargo due to the war, which was a total embargo, it would seem the part of wisdom, to me, to continue that embargo long enough to develop the other 40 per cent of these coal-tar products and the other 500 or 600 dyes that are not made in this country.

SENATOR DEMANDS FACTS

Senator Watson, of Indiana, at one point during the hearing, gave expression to the following:

Men who are opposed to the embargo get themselves into a frame of mind where they are willing to believe that Germany is not making dyes, while the men who are in favor of an embargo get themselves into a frame of mind where they are willing to believe that unless we enact some legislation soon Germany will flood us with dyes in thirty days and thereby destroy the dye industry in America. Why do you not get down to facts and tell us whether the American industry can be saved in the absence of an embargo and whether or not the American valuation plus a certain rate will protect the American industry?

Chemical Warfare Training Plan Outlined

The War Department has issued the following order to govern the training and the instruction of the Army in chemical warfare:

1. The conduct of a special service school for the training and instruction in chemical warfare, both offensive and defensive, for the following:

(a) Selected officers of the Chemical Warfare Service for preparation for duties as gas officers for divisions, corps and armies and for other technical duty in the Chemical Warfare Service.

(b) Selected non-commissioned officers of the First Gas Regiment for preparation for emergency commissions.

(c) Selected officers and non-commissioned officers of combatant arms in the duties of regiment and battalion gas officers and non-commissioned officers. Officers and non-commissioned officers so instructed will be available as instructors in chemical warfare in their own units.

(d) Selected officers and non-commissioned officers of the National Guard and Organized Reserves for duty as stated in paragraph (c) above.

2. Provision for officers of the Chemical Warfare Service as instructors in both offensive and defensive chemical warfare at General Service Schools and at certain Special Service Schools as directed by the War Department.

3. Provision for personnel of the Chemical Warfare Service for representation upon the staffs of corps areas, departments and divisions.

4. Provision for the availability of such portions of the First Gas Regiment as are necessary for demonstrations and for instructional purposes at Special Service Schools.

5. Provision for suitable units of special gas troops for corps areas and departments during periods of field training and the operation of such troops during these periods.

Joint Meeting of T.A.P.P.I. and Paper Mill Superintendents

The joint fall meeting of the American Pulp and Paper Mill Superintendents' Association and the Technical Association of the Pulp and Paper Industry will be held at Washington, D. C., York, York Haven and Spring Grove, Pa., Oct. 18 to 21, 1921. Closing meetings will be held at Philadelphia and Wilmington. As now arranged, the first day of the meeting will be spent in Washington with headquarters at the industrial building of the Bureau of Standards. The second day will include mill and plant visitations in York, York Haven and Spring Grove, the third day will be spent in Philadelphia and the fourth in Wilmington.

A revised draft of the program of meeting and mill visitations follows:

TUESDAY, OCTOBER 18

9 a.m.—Assembly at industrial building of the Bureau of Standards for reading and discussion of papers and group meetings arranged by T.A.P.P.I. Service Committee, and committee of A.P. & P.M.S.A.

12:30 p.m.—Luncheon, Bureau of Standards.

2 p.m.—Inspection of sections of the Bureau of Standards; visits to paper and dye laboratories of the Bureau of Chemistry; optional visits to Government Printing Office, Bureau of Engraving and Printing, and mill of District of Columbia Paper Manufacturing Co.

7 p.m.—Supper at New Willard Hotel, followed by smoker and continuation of papers, group meetings and discussions.

12 p.m.—Take Pullman cars for York, for visits to York, York Haven and Spring Grove, Pa.

WEDNESDAY, OCTOBER 19

Breakfast on arrival at York. Visits to plants in York and York Haven, followed by trip in afternoon to Spring Grove. Leave York for Philadelphia in evening.

THURSDAY, OCTOBER 20

Breakfast in Philadelphia at Bellevue-Stratford, association headquarters, where members and guests will register for visits to the various mills and plants to be inspected during the day.

7 p.m.—Banquet at Bellevue-Stratford.

FRIDAY, OCTOBER 21

Excursion to Wilmington, Del. Leave Philadelphia for Wilmington by early train. Breakfast at cafeteria of Pusey-Jones Co. on arrival, followed by visits to following plants: Pusey-Jones Co., du Pont company's plant at Carney's Point, inspection of laboratory of dye works of the du Pont company.

The chairman of the local committee of arrangements is Fred A. Curtis, chief of paper section, Bureau of Standards, Washington, D. C.; Grellet N. Collins, of Dill & Collins, Philadelphia, is in charge of arrangements for Philadelphia district; W. S. McClellan, of P. H. Glatfelter Co., for the York district, and Harvey G. McDowell for Wilmington.

American Tar Products Co. to Build New Chicago Plant

The American Tar Products Co., a \$5,000,000 corporation with plants in St. Louis, Milwaukee, Youngstown, Birmingham and Steubenville, Ohio, has purchased approximately forty acres at the southwest corner of Pershing Road and Fifty-second Ave., Chicago, upon which it will construct a new plant. The ground has already been broken and contract entered into to purchase the byproducts of the Chicago Byproducts Coke Co., materials being conveyed by pipeline from the latter plant. The operations carried on will involve the reduction of a large number of byproducts from coal tar, including roofing, waterproofing, wood preservatives, creosote oil and other products. An extension of the Illinois Central R.R. is to be constructed into the plant, which is also located on the Chicago & Illinois Western R.R. and the drainage canal. This company is building barges to carry raw materials from points on waterways to the plant and also will have several hundred tank cars in operation. Samuel H. Bingham is president of the company.

Chemical Exposition Notes

GLASS AND PORCELAIN

Glass and porcelain for the chemical industries will occupy an important position in the exhibits at the Seventh National Exposition of Chemical Industries, to be held in the Eighth Coast Artillery Armory, New York, Sept. 12 to 17. There will be a remarkable display covering a wide range of optical measuring instruments, photomicrographic apparatus, photographic lenses, microscopes, projection apparatus, ophthalmic lenses and instruments, range finders and gun sights, searchlight reflectors, stereo-prism binoculars, magnifiers, cups and cylinders.

A complete exhibit of glass enameled iron and steel equipment, small laboratory utensils, stills, evaporating dishes, condensers, cascade dishes, vacuum pans, autoclaves and tilting kettles will also occupy space, where reduction of costs and improving operations will be explained by experts.

Chemical and scientific porcelains for laboratory uses will hold a place of importance. Special stress is laid on heat resistance in these wares. Crucibles which do not crack or become unfit for use after several heats are of great interest to the chemist or scientific experimenter.

It is reported that dishes made from a glass composition which is entirely unaffected by nitric, sulphuric and hydrochloric acids, regardless of temperature or concentration, and offers great resistance to the action of phosphoric acid, casseroles perfected to meet the requirements of chemical and steam baths, will be a part of this display.

New Chemical and Oil Companies

During the month of July a total of twenty-nine companies was organized, with capital of \$50,000 and over, to manufacture chemicals, chemical byproducts, drugs, dyes and affiliated products. The aggregate capitalization was \$3,265,000, representing a slight decrease as compared with the corresponding figures for the month of June, set forth in a recent issue of *CHEMICAL & METALLURGICAL ENGINEERING*. The decline, as compared with the same month of 1920, is marked, for in July, 1920, the total capitalization of chemical organizations reached \$21,475,500. For the first seven months of the present year the total indicated investment of new companies in this line stands at \$68,890,000; the figures for the same period in 1920 approximate \$131,207,000.

During the same month sixty-nine companies were chartered with capital of \$50,000 in the oil industry, with total indicated capitalization of \$38,777,000, the smallest figures for any month of the present year. As compared with the preceding month of June, the decrease was \$13,843,000. In July, 1920, a year ago, the record was \$116,841,000.

European Nitrogen Developments

A supplementary report issued by the British Nitrogen Products Committee states that Brunner Mond & Co., Ltd., in addition to taking over the government factory at Billingham, has organized a subsidiary company, which is concentrating its attention on the design of a new nitrogen-fixation plant with an annual capacity of 7,000 tons of fixed nitrogen. It is also reported that a company to be known as Cumberland Coal, Power & Chemicals, Ltd., has been organized for the purpose of manufacturing synthetic ammonia under the patents of the Claude process.

Germany's productive capacity for synthetic ammonia in 1920, according to a report just issued by the German Government, was 424,000 tons, as compared with 247,300 tons for the rest of the world.

Pottery Workers Accept Wage Reduction

At a conference between the United States Potters' Association and the National Brotherhood of Pottery Operatives at Atlantic City, N. J., Aug. 5, the employees agreed to an immediate reduction of 10 per cent in wage scale, with an additional 9 per cent reduction in January, 1922. At the different sessions it was set forth that the pottery industry at the present time is operating at less than 50 per cent of normal, without very encouraging outlook for early resumption.

Plans for the Symposiums on Gas Chemistry and Filtration at New York Meeting, A.C.S.

The plans of the Division of Industrial and Engineering Chemistry of the American Chemical Society outline two series of papers and discussions which should prove extremely interesting to many industries. The symposium on gas chemistry, which will be held on the afternoon of Sept. 8, will be devoted to four principal subjects: Coke-oven problems, low-temperature carbonization, gas works control, and gas analysis and its applications.

FORMATION OF SECTION ON THE CHEMISTRY OF GASES AND FUELS IN PROSPECT

If the interest in the program and problems presented at the symposium seems to justify it, plans may be made for the formation of a regular section of the society to deal with the chemistry of gases and fuels. It is emphasized by the committee in charge of the meeting, C. H. Stone, H. E. Howe and R. S. McBride, that the symposium will deal with the chemical problems rather than with engineering problems which are commonly considered at the meetings of the American Gas Association. However, it is hoped that the co-operation and attendance of all engineers as well as chemists will be had.

Further suggestions regarding speakers or subjects which receive attention at the meeting should be addressed to the secretary of the symposium, R. S. McBride, 610 Colorado Building, Washington, D. C. Those having articles which they desire to present at the September meeting on any phase of gas or fuel chemistry should send the abstract of their paper with title and author to H. E. Howe, Marine Biological Laboratory, Woods Hole, Mass., on or before Aug. 18.

FILTRATION SYMPOSIUM

Dr. D. R. Snerry, who has organized the symposium covering the different phases of filtration, announces that sixteen papers have already been promised for presentation at the meeting.

All papers are to be illustrated with lantern slides, whenever possible, and a full opportunity will be given to members to question the authors.

The subjects to be treated include: Theory of filtration, rates of flow, general operating experiences, filtration apparatus, general engineering experiences, filter bases, plate and frame filter presses, suction filters, dumping filters, squeezing filters, centrifugal filters, pulp filters, new ideas in filtration apparatus, filter cloths, filter papers, filter alloys and crystalline filter bases.

Wilkes-Barre Meeting of the American Institute of Mining and Metallurgical Engineers

The semi-centennial anniversary meeting of the American Institute of Mining and Metallurgical Engineers will be held at Wilkes-Barre, Pa., Sept. 12-15, 1921. Anthracite coal and its production will be the chief subject to be discussed, although a number of interesting papers are scheduled to be read before the Metal Section of the Institute. Convention headquarters will be at the Irem Temple.

PROGRAM OF THE MEETING

R. V. Norris is the general chairman of the local committee, of which Paul Sterling is the general secretary. The program of the meeting follows:

MONDAY, SEPT. 12

Coal Section

2:30 p.m.

- "Mechanical Mining of Anthracite," by H. D. Kynor.
- "The Ashley Planes," by C. H. Stein.
- "Anthracite Preparation," by D. C. Ashmead.
- "Anthracite," by Donald Markle.
- "The Slush Problem," by John Griffen.

8 p.m.

- "The Lynch Plant," by Howard N. Eavenson.
- "General Description Anthracite Field," with maps and sections, by E. W. Parker.

Metal Section

8 p.m.

- "Application in Rolling of Effects of Carbon, Phosphorus and Manganese on Mechanical Properties of Steel," by W. R. Webster.
- "Thacher Process for Molding and Casting Propeller Blades and Wheels," by E. Touceda.
- "Making a 5 per cent Nickel-Cast-iron Alloy in an Electric Furnace," by D. N. Witman.

TUESDAY, SEPT. 13

In the morning automobile trip through Wyoming Valley, visiting breakers and mine plants. Leave Irem Temple, 9 a.m. sharp.

Luncheon as guests of the International Correspondence Schools, Scranton.

At 2 p.m. Technical Session in International Correspondence Schools auditorium.

Discussion on "Mine Fires," by Douglas Bunting.

"Electric Power a Factor in the Anthracite Field," by W. A. Thomas.

"Determination of Electrical Equipment for a Mine Hoist," by Graham Bright.

"The Automatic Substation for Coal Mines," by R. J. Wensley.

Also at 2 p.m. Americanization Session. Meeting of Committee on Industrial Relations for discussion of papers. Discussion will be introduced by E. E. Bach, Director of Americanization for State of Pennsylvania, and chairman of Institute subcommittee on Americanization.

Return to Wilkes-Barre by special train on Laurel Line. 8 p.m.

"The Hoisting Plant of the Pittsburgh Terminal Railroad-Coverdale Mine," by M. D. Kirk.

"Power Installation at Coverdale," by C. M. Means.

"Octagonal Ventilation Shaft of Davis-Daly Copper Co.," by J. L. Bruce.

"Application of Pulverized Coal to Boilers," by J. M. Fuller.

WEDNESDAY, SEPT. 14

9 a.m. and 2:30 p.m.

General joint meeting conducted by Society of Economic Geologists.

Papers of the Society of Economic Geologists and the following papers of the Institute:

"Stratigraphy of the Anthracite Region." Discussion led by James F. Kemp.

"Petroliferous Rocks in the Serra da Baliza," by E. P. de Oliveira.

"General Geology of Catorce Mining District," by C. L. Baker.

"Geology of the Namma Coal Field," by Edel Moldenke.

9 a.m.

Session on Mine Accounting. "Capitalization and Valuation of Mine Development," by J. B. Dilworth. (Discussion).

Luncheon. Complimentary to members and guests of the Institute at the Wyoming Valley Shovel Works.

General Technical Session

2:30 p.m.

"Queen Nine-hearth Roaster," by J. Moore Samuel.

"Flotation of Pyrite," by W. S. Morley.

"Relation of Gypsum Supplies to Mining," by D. H. Newland.

(Members may attend, instead, trips as arranged by the Ladies' Committee.)

8 p.m. Dinner and ball at the Irem Temple given to the visiting Institute members by the Anthracite Section.

THURSDAY, SEPT. 15

All-day excursion by automobile, starting from Irem Temple at 9 a.m. sharp. Lunch en route.

FRIDAY, SEPT. 16

Visits to points not provided for in the program will be arranged for, as far as practicable, after adjournment on Friday, if members will make their desires known to the local committee.

New Chemical Laboratory, Yale University

The new chemical laboratory at Yale University, New Haven, Conn., contract for which has recently been awarded to the Thompson-Starrett Co., 49 Wall St., New York, will occupy a portion of the Pearson-Sage Square, near the present Sloan Physics Laboratory. It will have a ground floor area of about two acres, with extensive space given over to private research laboratories, general chemical laboratories, recitation rooms, lecture rooms and library. The exterior will be of brick and brownstone, with slate roof to harmonize with neighboring structures. The building will be known as the Sterling Chemical Laboratory, and is estimated to cost about \$1,500,000.

Zinc Dust in 1920

The zinc dust produced in the United States in 1920, as reported to the U. S. Geological Survey by twelve plants, showed an increase in 1920 as compared with 1919 of over 70 per cent in both quantity and value.

ZINC DUST PRODUCED IN 1919-1920

	1919			1920		
	Quantity (Short Tons)	Value Based on Sales	Average Price per Lb. Cents	Quantity (Short Tons)	Value Based on Sales	Average Price per Lb. Cents
Prepared "Blue powder"...	4,083	\$801,366	9.8	9,066	\$2,009,117	11.1
"Atomized" zinc dust.	2,515	524,694	10.4	2,273	512,833	11.3

Personal

N. E. AUSTIN, of New York, has resigned as treasurer of the Triangle Commercial Corporation, to become connected with the Eli Chemical Products Co., Inc., 206 East 128th St.

G. A. BOLE has resigned his position as professor of chemistry at Alfred University, Alfred, N. Y., to become associated with the ceramic station of the Bureau of Mines at Columbus, Ohio.

J. P. BONARDI has resigned from the Bureau of Mines, with which he has been associated for the past five years, to accept the position as manager of the assay and chemical department of the Mine & Smelter Supply Co., Denver, Col., beginning his new duties Aug. 15.

WILLIAM BURGESS, of Trenton, N. J., recently appointed by President Harding as a member of the Tariff Commission, has resigned as vice-president of the United States Potters' Association. The office will be filled at the next annual meeting of the organization to be held at Washington, D. C., in December.

W. A. DALZELL, of Moundsville, W. Va., has been re-elected president of the Fostoria Glass Co. C. B. Roe has been re-elected vice-president and general manager.

Baron GERARD DE GEER has left the Domnarfvet Steel Works and is now manager of Nyhammars Bruks Aktiebolag, Nyhammar, Sweden.

J. R. DAVIES, formerly secretary of the Chicago Section, American Chemical Society, has been appointed chief chemist and assistant plant manager of the chemical works of the Calumet Baking Powder Co. at Joliet.

L. I. LOGHRY has resigned from the Mount Joy Magnesia Co., Mount Joy, Pa., and has accepted the position of chief chemist for the Knickerbocker Portland Cement Co., Hudson, N. Y.

G. ST. J. PERROTT, associate physical chemist of the United States Bureau of Mines Experiment Station, Pittsburgh, Pa., is to be sent to Birmingham, Ala., to study the physical properties of coke in relation to its production and use in the blast furnace.

W. N. ROACH, formerly engaged in patent work for the War Department, has left that service to start a private patent practice in Washington. Mr. Roach has been with the War Department since August, 1918.

L. I. SHAW, assistant chief chemist of the Bureau of Mines, has transferred his activities from Washington to the ceramic station at Columbus, Ohio, to co-operate with R. T. Stull in research on ceramics. His immediate work will be concerned with physical chemistry as applied to ceramics and involves work with colloids.

R. J. TAIT, chemist for the Grasselli Chemical Co., New York, has been transferred to the Cleveland, Ohio, office of the company, to be connected with the sales department there.

Obituary

DR. WALLACE CALVIN ABBOTT, president of the Abbott Laboratories, which he founded and built into one of Chicago's most prominent chemical establishments, died at his home on July 4. Born in 1857, he was educated at Dartmouth College and took the degree of M.D. at the University of Michigan in 1885. Dr. Abbott was a pioneer in the field of alkaloidal medication, and his incessant labors through his writings and his personal contact have made his influence on the medical profession in this respect profound. Dr. Abbott was co-author, with Dr. William F. Waugh, of "The Practice of Medicine" and of "Positive Therapeutics." He was editor-in-chief of *The American Journal of Clinical Medicine*, now in its twenty-eighth year.

GEORGE H. ELLIS, vice-president of the Chicago Section of the American Chemical Society in 1900, died on July 10. Mr. Ellis belonged to the earlier generation of chemists who did much for the development of industrial chemistry in the West. He was born in 1864 and received the B.Sc. degree from the University of Illinois in 1885. As chemist for the C. B. & Q. R.R. from 1885 to 1893 he acquired sufficient experience to establish himself as a consulting chemist, maintaining an office in Chicago for ten years thereafter. A great deal of his attention was devoted to the paint trade, and in 1903 he became secretary and treasurer of the George W. Pilkington Co. In 1909 he was elected president of the Johnson Magnetic Paint Co., which office he held until his death. He was the author of "Notes on White and Tinted Paint Analysis."

HARRY M. GRAY, president and general manager of the Como Chemical Co. of Kokomo, Ind., a member of the Chicago Section, A.C.S., died at Kokomo on July 3.

PROF. CHARLES L. WEIL, consulting engineer, died at his home in Port Huron, Mich., July 16. Prof. Weil was actively identified with the Diamond Crystal Salt Co. as consulting engineer, and in addition maintained an engineering office in Port Huron. He was born in North Andover, Mass., in 1865. His engineering education was obtained in the Massachusetts Institute of Technology, from which he graduated in 1888. After a short period as draftsman with the Worthington Pump Co. he became instructor at Lehigh University, leaving there in 1893 to take charge of the engineering department of Michigan Agricultural College, where he remained for thirteen years. During his connection at M.A.C. Prof. Weil designed and installed a complete new power plant for the college which was a model of its kind at the time and most of which is still giving satisfactory service. He also instituted many important changes and improvements in the engineering department of the college. From M.A.C. Prof. Weil went to Detroit to engage in consulting work, later moving to Port Huron on account of the close connection which he established with the Diamond Crystal Salt Co. at St. Clair, at the same time continuing his consulting practice. Prof. Weil was probably the country's foremost engineer in the evaporation and manufacture of salt. His work was not limited to this phase of engineering, however, as he was active along many other lines, particularly power plant work. He was a member of the Detroit Engineering Society, Michigan Engineering Society and the American Society of Mechanical Engineers.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Aug. 15, 1921.

The chemical market during the past week presented no signs of pressing liquidation which seemed so persistently continuous early in the year and there was a little indication of speculative activity. The closing prices as a rule were very near the finals of the previous week. Prices generally are firmer, and although buying orders are still limited to small lots, as before, the number of such lots has been on the increase. Occasional orders for carlot quantities were heard during the week, especially in the cases of soda ash and fused sulphide of soda. Business all around would be much better were it not that the month of August is known as a vacation period and apt to be featured by the dullest trading of the year. Barium chloride buyers are becoming more confident as they realize that domestic makers will be unable to compete with importers' prices. Imported goods in most lines still figure largely on the market. Light soda ash did not vary much. Solid caustic soda touched \$3.60 per 100 lb., which is the lowest figure recorded for the past few months.

Bichromate of soda held its own around formerly quoted prices and prussiate of soda was firm around 11½c. per lb. Borax is finding a better market and leading producers say that considerable improvement has taken place in the amount of buying. The demand for this chemical has emanated from various sources. Muriate of potash was a shade easier and quiet. Bleaching powder is moving in very good shape at the works, with spot material rather scarce and prices firmer. Arsenic is experiencing the usual dullness incident to this period of the year. Consuming industries have not shown much departure from the conservatism lately displayed. Sales of several carlots of fused sodium sulphide were made around 5½c. per lb. It is believed that these purchases were made for use in the dye trade. Fair trading in imported caustic potash was noted around 4½c. per lb. Soapmakers are buying this material. Caustic soda and soda ash have also prompted attention from leading soapmakers. Paper mills have bought quantities of bleaching powder at the works. Enamellers are showing more interest in borax. Textile mills are taking on miscellaneous supplies of chemicals and dyestuffs, but are not inclined to operate far ahead. Tanneries are showing more interest in the market and laundry supply houses are taking on moderate quantities of oxalic acid and Japan wax.

CHEMICALS

Calcined carbonate of potash, 80-85 per cent, is obtainable at prices ranging from 5@5½c. per lb. The market is generally quoted at the outside figure by sellers. The movement has not involved large proportions during the past week, as buyers appeared satisfied to operate from hand to mouth. Higher grades are quoted up to 6½c. per lb., depending upon the quantity. Sales of imported caustic potash, 88-92 per cent, have been reported at 4¼@4½c. per lb., and it is possible that 4c. would be accepted in some directions on a firm offer for a round lot. Consumers have taken on large quantities of this chemical and are showing fair interest in additional supplies. Competition is naturally keen to get what business is passing and this is accountable for the irregularity displayed in quotations. Prominent sellers of imported muriate of potash quote the market at 85@90c. per unit of K₂O. This is equivalent to approximately \$42.50@\$45 per ton. The market has been a tame affair with inquiries and offerings rather limited. Rumors are current that domestic barium chloride makers are seriously considering the abandonment of further attempts to manufacture, in which case they expect to take over agencies for foreign producers. Prices now named for spot delivery of imported prime white material is \$52 per ton and shipment goods is offered openly as low as \$46 per ton. Buyers

are much more confident in the market at these figures and sales in good quantity are reported by all holders. Domestic makers were not offering or quoting any material. Resale caustic soda of standard make has sold at prices extending from \$3.60@\$3.70 per 100 lb. The inside price was quoted ex-store and the outside ex-dock. Dealers have experienced a fair call for this chemical for domestic use, but transactions have been similar to those of other items—namely, small lots. At the works, producers quote 3¼c. per lb., basis 60 per cent, for contracts.

Prices on ammonium carbonate are somewhat lower at 7@9c. per lb., according to quantity and grade. Prices on permanganate of potash are lower from importers at 25@27c. per lb. A slow demand was noted. Prominent copperas dealers offer prime green crystals on the basis of \$19@\$20 per ton in barrels and \$17.50 per ton f.o.b. works in bags. Activity has not been along elaborate lines, but the market appeared quite steady at the above-named prices. Spot prices of oxalic acid have been lowered in some directions and sales of both foreign and domestic from 17c. down to 16¼c. per lb. It was stated that offerings of foreign material were scarce at the close, as the embargo is having a tendency to hold supplies. Producers report sales at 17½c. per lb. and upward, depending upon the brand and quantity. The inquiry for sulphate of ammonia has remained dull throughout the week and consumers are apparently satisfied to let the market take care of itself temporarily. Prominent sellers stated that they were asking \$2.15 per 100 lb. for goods in bags, but they would probably accept a shade under this price on any kind of a firm offer for a round lot. Occasional sulphuric acid sales of the 60 deg. Baumé went through at \$11@\$13 per ton, according to seller. Rumors were heard that sales have been put through f.o.b. works a shade under the inside price. The 66 deg. sulphuric acid is quoted at \$18@\$20 per ton. Business in arsenate of lead is showing the usual midsummer dullness after a period of fair recovery. A satisfactory volume of business was placed with the insecticide trade, but the bulk of demand has been satisfied. Manufacturers offered the paste at 9c. per lb. and the powdered at 15@17c. per lb., according to quantity. Alcohol buying is confined to small quantities with consumers still showing hesitation about placing orders for bulk lots. Prices are nominal and in general will be maintained, although some shading is occasionally done on firm business. Ethyl, 188 proof, is quoted at \$4.65@\$4.75 per gal.; denatured, 180 proof, is 31@32c. per gal.; 188 proof, 35@36c. per gal, and 190 proof, 37c. per gal. Methanol is 78c. per gal. for the 95 per cent and 80@88c. for the 97 per cent.

COAL-TAR PRODUCTS

Business has been very dull for the handlers of coal-tar products during the past week. The topic of principal interest has been the tariff, and few firms concerned have not sent representatives to Washington to give their views of the case. Immediate interest attaches to the efforts to extend the emergency tariff bill until such time as final action on the Fordney bill might be taken. Further efforts are being made to have the Senate include the licensing provision in the present measure. In the meantime, attempts to sell goods in the spot market are sporadic and few buyers are coming into the market without strong inducements. There were some reports of business with export buyers. Benzene is still scarce, although the limited scale of consuming operations has prevented any sharp advances. Makers' quotations are unchanged at 27@33c. per gal. Resellers who have supplies are able to demand premiums over these figures. One of the large consumers of naphthalene offered a heavy lot of crushed material in the market and found buyers at 6¼c. per lb. Refiners' prices are held at former levels, but without any business of consequence. The consuming demand for phenol has taken the greater part of all the low-priced material that was recently offered in the market and it is possible that 10c. per lb. is the present low price. It may be possible that on a firm offer bids of 9½c. per lb. would not be refused. Makers' prices on H acid continue to rule in the absence of activity. Quotations are given as \$1.15@\$1.25 per lb., although it is possible that outside holders can offer limited quantities at concessions.

Manufacturers quote technical *sulphanilic acid* at 27@30c. per lb., according to quantity. Interest is scattered with a few small lots moving. Further signs of weakness in *beta naphthol* are evident in the stand of makers. While no definite defections are admitted by producers, a keen rivalry exists, with each cutting prices for new business. The resale market is quoted at 32@35c. per lb., according to quantity. A few sales of comparatively small lots have been put through, but little consuming demand is noted. The resale market in *dimethylaniline* is practically bare of stocks, but some makers have reduced prices to 45c. per lb. in lots of 10 drums or more and are doing some business at this figure. Other makers quote 60@65c. per lb., according to quantity, but admit that they are not pushing sales. Occasional inquiries are coming into the market for limited quantities. The market on *diphenylamine* is firm in makers' hands at 65@70c. per lb., with resale lots cleaned out. Small lots of *paranitraniline* in resellers' hands have moved recently at 75c. per lb., but the quantities offered at this figure are trifling and have not affected the manufacturers' market of 79@82c. per lb. Interest has been slow. Prices on *aniline oil* have been steady at recent levels. Makers will do 20c. per lb. on firm business in returnable drums. Outside lots of more or less inferior quality can be had in reasonable quantity as low as 18c. per lb.

VEGETABLE OILS

A good inquiry was reported for *chinawood oil* for nearby as well as forward delivery, and with cables from primary sources higher, the undertone at the close was quite firm. Scattered sales of less than carlots were reported at 14c. per lb., while prompt shipment oil from points near by sold on the New York equivalent of 12½c. per lb. For September arrival at New York 11½c. was asked, with August-September shipment from the Orient quoted nominally at 11½c. per lb. c.i.f. New York. Internal difficulties in China may result in a smaller movement of oil to the ports and operators here believe that a shortage in the supply may exist later on. A sale of 500 tons of *Manila coconut oil* for September shipment was reported on the basis of 7½c. per lb., loose, c.i.f. San Francisco. Further offerings were reported on this basis during the week, although a generally firmer feeling was in evidence in sympathy with the strength in copra. A sale of 15 tanks of domestic Ceylon type oil was put through at 8½c. per lb., sellers' tanks, f.o.b. Jersey City. Sales of crude *corn oil* went through during the week at 7c. per lb., sellers' tanks, f.o.b. point of production, Middle West. The market closed firm, with asking prices ranging from 7¼@7¾c. per lb., f.o.b. mills. The market for *edible olive oil* was irregular on selling pressure from abroad and nominal prices for high-grade material on spot ranged from \$1.80@\$2.25 per gal. Denatured oil on spot closed at \$1.20 per gal. The recent rise in exchange, coupled with higher cables from Liverpool, caused prices to hold firm despite the inactivity of large operators. *Lagos oil* on spot sold in a small way as high as 7½c. per lb. *Lagos* for shipment settled at 6¾c. asked c.i.f. N. Y., with niger quoted at 5¾@5¼c. per lb. Prices on *linseed oil* are quoted lower on a sharp slump in the Argentine seed market. Quotations are based on 73c. per gal. in barrels, carload lots. Buyers are showing little interest except in small lots for prompt and no interest at all in future deliveries. Offerings of crude *peanut oil* were scanty, and the market closed with prices on the domestic products more or less nominal at 7¼@7½c. per lb., tank cars, f.o.b. mill. Oriental oil for August shipment from the Coast held at 7½c. per lb., tank car basis.

The Chicago Market

CHICAGO, Aug. 12, 1921.

There was no change in the demand for industrial chemicals during the past two weeks. Dealers report a fair volume of small orders and are apparently satisfied with the movement of their stocks. There is no difficulty in procuring supplies of most items and as a rule prices are unchanged. Buyers are showing no tendency to anticipate on their requirements and are buying supplies only for immediate consumption.

The demand for *caustic soda* continues light with no change in price noted. The solid 76 per cent is available

at \$4@\$4.10 per 100 lb. and the ground at \$4.65@\$4.75. Supplies are small with little or no pressure to sell. The request for *soda ash* improved somewhat and prices were steady at \$2.60 per 100 lb. for barrels. *Sal ammoniac* continued quiet and supplies were available at 7½@7¾c. per lb. for the white granular. There was no improvement in the demand for *carbon tetrachloride* and the price was unchanged at 11c. per lb. *Carbon bisulphide* was quiet and easy at 6¾@7c. per lb. The movement of *formaldehyde* was slow and supplies were plentiful at 13½c. per lb. for barrels. *Glycerine* was quiet with the inquiry light and few sales reported. Material c.p. was offered freely at 14½c. per lb. for single drums. *Iron sulphate* was in fair request and small sales were noted at \$1.90 per 100 lb. *Lead acetate* was in poor demand with supplies available at 13c. per lb.

A better inquiry was noted in some quarters for *caustic potash*, one dealer reporting a good volume of small orders at 6½c. per lb. for the 88-92 per cent material. *Bichromate of potash* was available at lower prices and moved better in some directions. The prevailing quotation was 14c. per lb. for spot goods. Supplies of *sodium bichromate* were smaller with the inquiry improved. Several small sales were noted at 9½c. per lb. Small sales of *sodium acetate* were reported at 4½c. per lb. *Bicarbonate of soda* was unchanged as to price and a fair movement was noted at \$2.60 per 100 lb. Dry *bisulphite of soda* was offered at 6c. per lb. in single barrel lots. *Hyposulphite of soda* was quiet and unchanged as to price. Pea crystals were available at \$4.05 per 100 lb. Supplies of imported *zinc chloride* were offered at 8½c. per lb. in single cask lots.

There were no developments of consequence in the acid market, the prevailing tone being quiet with prices steady. The 28 per cent commercial grade of *acetic acid* is moving in a fair way at \$2.50@\$2.75 per 100 lb. for barrels. *Glacial acetic* is extremely quiet and supplies are offered at 9¾@11c. per lb. according to the quantity and holder. *Oxalic acid* is in brisk demand and 18c. per lb. appeared to be the inside quotation on spot goods. The heavy acids are in slightly better request and firm as to price. *Sulphuric acid* is quoted at \$19@\$20 per ton in tank cars f.o.b. works.

VEGETABLE OILS

Trade in *linseed oil* failed to show any marked improvement, although the inquiry was reported as fair from the smaller consuming trade. Small lots of the boiled are quoted at 77c. in drums with the usual reduction for the raw.

NAVAL STORES

Business in the naval stores market was of a quiet character the last few days. Small sales of *turpentine* were noted, but nothing in a large way. The market on turpen-

The Iron and Steel Market

PITTSBURGH, Aug. 12, 1921.

Demand upon the steel mills continues to increase, although very slowly. At the middle of July, marking the low point in production, steel production was at slightly under 20 per cent of capacity, while the increase, roughly speaking, is at the rate of one or two points a week. Continuance of the present improvement seems well assured, but would mean a rate of no more than 35 or 40 per cent by November. With improvement in general business, freer inception of construction projects and railroad buying there would be additional improvement in steel demand, but it is quite uncertain whether such influences will be marked between now and the end of the year.

From the monthly report of the American Iron and Steel Institute, giving the steel ingot output of thirty large companies, it may be estimated that production in July was at average rates of approximately 18 per cent by the independents, 25 per cent by the Steel Corporation and 21 per cent by the steel industry as a whole, the rate being under 20 per cent at the middle of July, but increased by the present time to well above 20 per cent. The July production was at the rate of about 11,000,000 gross tons of steel ingots a year, actual production having been 40,881,392 tons today was 63c. per gal. in drum lots. *Rosins* were quiet and easy, the "G" grade being available at \$6.75 per 280 lb. for less than carlots.

in 1920 and 30,284,682 tons in 1912, the best year before the war. The best estimate of actual capacity seems to be 52,500,000 tons.

STEEL CORPORATION'S UNFILLED OBLIGATIONS DECREASE

The Steel Corporation's unfilled obligations decreased by 287,544 tons during July, to 4,830,324 tons at the end of the month. For five successive months these decreases have run just a little bit under the shipments, the differences between estimated shipments and decrease in unfilled tonnage averaging about 100,000 tons a month, or about 7 per cent of capacity. March shipments were at fully 50 per cent of capacity, while July shipments were at only about 25 per cent of capacity. The showing is precisely in line with the character of the corporation's business. In 1920, when the independents had largely advanced prices, the Steel Corporation accepted contracts from its regular customers such as were expected, roughly speaking, to carry the customers to the middle of the year. With the great decrease in activity it requires much longer to work out the contracts. In recent months the corporation has been receiving most of its business in the form of specifications against these contracts, and with declining prices these specifications have been the subject of negotiation. The independents, on the other hand, obtain most of their business in the form of strictly new orders.

The downward sequence in the degree of market activity is approximately as follows: Sheets, bars, tubular goods, wire products, tin plates, plates, structural shapes, rails. Sheet mill operations are above 30 per cent of capacity, while rail production is almost nil.

DEMAND FOR STEEL PRODUCTS INCREASING SLOWLY

Demand for steel products continues to increase slowly, and is expressed almost wholly in small-lot business, largely carloads, for as prompt shipment as can be made, and this means in many cases shipment within two or three days of receipt of the order, a fortnight being an unusually long period. Thus, whether buyers have "confidence" in the future of prices or not, they are taking very little risk. What they have confidence in is their ability to liquidate their purchases promptly and collect the money.

A close analysis of prices for steel products generally indicates that while there was a more or less steady decline for months the condition at present and in the past week or two is that of prices having barely a sagging tendency. There is no thought that prices will advance from the present level, but the lowest point under present cost conditions is not far away. By "cost" is not meant the actual cost at present, with the overhead and other expenses falling upon a very small production, but the cost with a fair operating rate and present wage rates, freight rates and other factors.

PRICES

Regular prices, generally applicable to carload lots, are: Bars, 1.75c.; shapes and plates, 1.85c.; hoops and bands, 2.40c.; blue annealed sheets, 2.40c.; black sheets, 3c.; galvanized sheets, 4c.; plain wire, 2.50c.; wire nails, \$2.75. On particularly desirable orders most if not all of these prices are subject to concessions, but the concessions are only \$1, \$2 or \$3 a ton and as to bars, shapes and plates the concessions are hardly any larger than buyers were able to obtain a fortnight ago. Thus it is not entirely certain that the market is even sagging, whereas until quite recently it was very plainly declining. A broadening in the market, with orders offered in larger sizes, may bring about lower prices, but only by small margins. With present wages and freight rates the average price of finished steel products is unlikely to go \$5 a ton below prices now quoted as regular, these prices already being subject to some concessions, as indicated.

Pig iron shows a slightly steadier tone, attributed to stocks of bessemer and foundry grades having become relatively small, though there is still plenty basic. The valley market remains quotable at \$20 for bessemer, \$18 for basic and \$19.50 for foundry. A sale of 500 tons of bessemer was made this week at \$21.44, delivered Pittsburgh, or 52c. under the equivalent on valley iron, as the valley-Pittsburgh freight is \$1.96.

General Chemicals CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.12 $\frac{1}{2}$ - \$0.12 $\frac{3}{4}$	\$0.40 - \$0.45
Acetone.....lb.	2.75 - 3.00	.13 - .13 $\frac{1}{2}$

Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.32 - .35
Beta-naphthylamine, sublimed..... lb.	1 75 - 1 80
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.68 - .75
Cresylic acid, 35-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1 20 - 1 25
Dimethylaniline..... lb.	.45 - .55
Dinitrobenzene..... lb.	.26 - .28
Dinitrochlorobenzene..... lb.	.20 - .30
Dinitronaphthalene..... lb.	.30 - .40
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.27 - .30
Dip oil, 25%, ear lots, in drums..... gal.	.40 - .45
Diphenylamine..... lb.	.65 - .70
H-acid..... lb.	1 15 - 1 25
Meta-phenylenediamine..... lb.	1 15 - 1 20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1 75 - 1 85
Naphthalene crushed, in bbls..... lb.	.06½ - .07½
Naphthalene, flake..... lb.	.08½ - .09½
Naphthalene, balls..... lb.	.08 - .09½
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3 10 - 3 20
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.80 - .85
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1 40 - 1 45
Para-amidophenol, HCl..... lb.	1 60 - 1 75

Para-dichlorobenzene..... lb.	15 - 20
Paranitroaniline..... lb.	75 - 80
Para-nitrotoluene..... lb.	85 - 95
Para-phenylenediamine..... lb.	1 70 - 1 95
Para-toluidine..... lb.	1 25 - 1 40
Phthalic anhydride..... lb.	50 - 60
Phenol, U. S. P., drums..... lb.	09 - 11
Pyridine..... gal.	2 00 - 3 50
Resorcinol, technical..... lb.	1 60 - 1 65
Resorcinol, pure..... lb.	2 25 - 2 30
Salicylic acid, tech., in bbls..... lb.	19 - 22
Salicylic acid, U. S. P..... lb.	20 - 25
Salol..... lb.	75 - 80
Solvent naphtha, water-white, in drums, 100 gal..... gal.	25 - 28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	14 - 16
Sulphanilic acid, crude..... lb.	27 - 30
Tolidine..... lb.	1 25 - 1 35
Toluidine, mixed..... lb.	40 - 45
Toluene, in tank cars..... gal.	25 - 28
Toluene, in drums..... gal.	28 - 31
Xylidines, drums, 100 gal..... lb.	40 - 45
Xylene, pure, in drums..... gal.	40 - 45
Xylene, pure, in tank cars..... gal.	45 - 45
Xylene, commercial, in drums, 100 gal..... gal.	33 - 35
Xylene, commercial, in tank cars..... gal.	30 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0 24 - \$0 25
Beeswax, refined, light..... lb.	27 - 28

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Flour Mills have plans under way for the construction of a new flour milling plant on a local site to be about 140 x 150 ft., and estimated to cost close to \$150,000.

GADSDEN—The Tri-City Gas Co. has completed plans for extensions in its generating plant to double the present capacity. Extensions will also be made in the distributing system. The work will be inaugurated at once.

California

MELROSE—The National Lead Co. of California has completed plans and will soon commence construction of a new unit at its plant for lead-refining operations. Headquarters of the company are at 485 California St., San Francisco.

TURLOCK—The Turlock Gas Co. will make improvements and additions in its plant on South Front St., to cost about \$50,000.

TRACY—Officials of the Chamber of Commerce are holding a series of meetings relative to the establishment of a municipal gas manufacturing plant. O. W. Smith is at the head of the project.

Connecticut

OAKVILLE—The Connecticut Rubber Co., Hartford, has acquired an existing factory building at Oakville, near Waterbury, for the establishment of a new plant for the manufacture of rubber tubes and other rubber specialties. A number of improvements will be made in the structure and equipment installed at an early date. It is expected to give employment to about 100 operatives for initial production. The company is now operating a similar plant at Yale, Okla.

NEW HAVEN—The Seamless Rubber Co., Inc., is adding to its working force for increased production. The company has recently taken on about 150 additional persons.

Florida

TAMPA—The Nu-Tex Brick Co., which has begun the construction of a local plant for the manufacture of brick and other burned clay products, has been incorporated under state laws as the Florida Nu-Tex Brick & Tile Co., with capital of \$200,000. It is expected to have the plant ready for operation early in the fall. W. B. Coarsey is president and general manager; and H. E. Lough, secretary and treasurer.

DADE CITY—The Florida Cane Syrup Co. has preliminary plans under way for the establishment of a new local works for the manufacture of cane sirups. The equipment installation, including grinding mill, conveyor apparatus, cooking vats, etc., is estimated to cost in excess of \$50,000. E. S. Slough is general manager.

Indiana

DUNKIRK—The Hart Mfg. Co., specializing in the manufacture of glass jars and containers, is completing the installation of new machinery for jar production. Present operations will be on a curtailed basis with full resumption expected in the near future.

Illinois

CHICAGO—E. F. Houghton & Co., Shields Ave., manufacturer of lubricating oils, etc., has awarded a contract to the Austin Co., 208 South LaSalle St., for the construction of a new 1-story building at 3524 Shields Ave., 37 x 100 ft.

CHICAGO—The Arabol Mfg. Co., 200 North Jefferson St., manufacturer of liquid glue, etc., is planning for the early occupancy of its new 1-story and basement plant on Fifty-fourth St., now nearing completion. It will be 60 x 100 ft., estimated to cost about \$25,000.

BLUE ISLAND—The American Wire Fabrics Co., 208 South LaSalle St., Chicago, has awarded a contract to A. and E. Anderson, 19 South LaSalle St., for the construction of its proposed new galvanizing plant at the Blue Island works to be 48 x 145 ft. With a warehouse building to be erected at the same time, the cost is estimated at about \$100,000.

Maine

GREENVILLE—The Great Northern Paper Co., Millinocket, Me., has awarded a contract to the H. P. Cummings Construction Co., Fidelity Bldg., Portland, Me., for the erection of its proposed new 1-story shop addition at Greenville, 100 x 218 ft.

Maryland

LUKE—The West Virginia Pulp & Paper Co. has commenced the erection of a new addition at its local mills.

BALTIMORE—The Co-operative Paper Box Co., recently organized, will install machinery in a local building for the manufacture of paper boxes and containers. It is proposed to develop an output of about 10,000 boxes per day. B. F. Garrett, 3502 Cottage Ave., Govans, Md., is president; A. W. Watson, 4916 Alhambra Ave., Baltimore, is manager.

Massachusetts

BOSTON—Tileston & Hollingsworth, 892 River St., Hyde Park, manufacturer of paper products, have awarded a contract to the Aberthaw Construction Co., 27 School St., for the construction of two additions to its plant, to the finishing department and machine building, respectively.

Michigan

KALAMAZOO—The Western Paper Makers' Chemical Co. will rebuild the portion of its plant destroyed by fire, July 21, with loss reported at about \$12,000.

PONTIAC—The American Forging & Socket Co., Branch St., has preliminary plans under way for the erection of a new 1-story foundry addition, 40 x 50 ft., estimated to cost about \$30,000.

New Jersey

GLOUCESTER CITY—Leroy A. Goodwin, P. A. Stewart and J. L. Blandy, members of the local board of directors of the Chamber of Commerce, are interested in the establishment of a local plant for the manufacture of newsprint paper, utilizing the former buildings of the Argo Mills, manufacturer of textile products. A company capitalized at \$1,000,000 is being formed by Frank Hummell, owner of the mill property, and associates. A list of machinery for installation at the plant has been arranged, and it is proposed to have the mill ready for service around the close of the year. The Chamber of Commerce has adopted resolutions approving the plans of the company and urging support.

New York

NEW YORK—The Tidal Osage Oil Co., a subsidiary of the Tidewater Oil Co., 11 Broadway, previously known as the Guffey-Gillespie Oil Co., operating oil refineries, etc., has arranged for a bond issue of \$3,500,000, the proceeds to be used for general operations, extensions, improvements, etc.

LONG ISLAND CITY—The Mirrorlike Mfg. Co., 203 Eighth St., manufacturer of polishes, has awarded a contract to Walter J. Bond, 333 Jackson Ave., Astoria, L. I., for the construction of its proposed new plant, 100 x 100 ft., on property recently acquired at Queens Blvd. and Buckley St.

NEW YORK—The United Oil Producers Corp., 347 Madison Ave., affiliated with the Middle States Oil Corp. and the Imperial Oil Corp., address as noted, has sold a bond issue aggregating \$4,000,000, to be used in part for extensions, improvements, general operations, etc., in connection with its oil refineries.

North Carolina

ROANOKE RAPIDS—The Armstrong Chaborn Co., manufacturer of pulp and paper products, is reported to be planning for the rebuilding of the portion of its mill recently destroyed by fire, with loss estimated in excess of \$100,000.

Ohio

CINCINNATI—The Piqua Straw Board Co., 515-19 Eggleston Ave. recently organized, has acquired the Piqua, O., division of the American Straw Board Co., including the plant at Tippecanoe City, O., and the subsidiary company of Cincinnati, known as the Queen City Paper Co. The new organization plans for extensive operations. C. H. Palmer is president.

Pennsylvania

UNIONTOWN—The du Pont Powder Co. is planning for the rebuilding of the press mill at its Oriental works, near Uniontown destroyed by fire, caused by an explosion Aug. 3.

Tennessee

BRISTOL—The Enterprise Foundry & Machine Works has acquired a local building for the establishment of a new plant. The structure will be remodeled and a large department equipped as foundry. The work, including equipment, is estimated to cost about \$45,000.

Texas

MEXIA—The Golden Star Refining Co. is reported to be planning for the erection of a new oil refinery on local site. The initial plant will have a daily capacity of about 6,000 bbl.

DALLAS—The City Council is having plans prepared for the installation of a new water-purification plant at the White Rock reservoir, to include chemical lines, chemical feed machines, filter equipment and auxiliary apparatus. A bond issue has been arranged to cover the cost. David Morey, Jr., 517 Prætorian Bldg., is engineer for the project. M. G. James is city secretary.

FORT WORTH—The Panther Machine Co., F. & M. Bank Bldg., has plans under way for the erection of a new local plant with extensive foundry department for the manufacture of brass, bronze, aluminum and other metal castings. The company recently increased its capital from \$25,000 to \$100,000 for expansion. S. Johnson is president and general manager.

Virginia

BRISTOL—The Enterprise Foundry Co. is planning for the early occupancy of its new local plant, comprising the former rolling mill of the Virginia Iron, Coal & Coke Co. Remodeling work is under way, estimated to cost about \$45,000, and the present works will be removed to the new site upon completion. Additional equipment will be installed.

Washington

ANACORTES—J. E. Jensen and associates have leased the local plant of the Washington Glass Mfg. Co. for the establishment of a new works for the manufacture of glass specialties. The plant will be remodeled and improved, and additional equipment installed.

West Virginia

MARTINSBURG—Spangler & Oyler, Gettysburg, Pa., manufacturers of fertilizer products, are planning for the rebuilding of their branch plant at Martinsburg, recently destroyed by fire.

HUNTINGTON—The West Virginia Foundry & Stove Works are completing plans for the erection of a new 1-story foundry at their plant, 50 x 120 ft. It is proposed to provide equipment to double the present casting output at the plant. Frank C. Roggess is manager.

Wisconsin

CASPER—The Midwest Refining Co. is planning for the rebuilding of the portion of its local plant, destroyed by fire, July 17, with loss estimated at about \$50,000.

CASPER—The Producers & Refiners Corp., Waterloo, Ia., operating the former plant of the Hawkeye Oil Co., is perfecting plans for the erection of a new oil refinery at Casper, with ultimate capacity of about 10,000 bbl. The first unit, ground for which will be broken at an early date, will have an output of about 3,000 bbl. per day. Continuous stills will be installed and all products taken from the crude oil with the

exception of lubricants and waxes. At a later date it is proposed to extend the works to include a wax manufacturing and lubricating oil plant. The entire project is estimated to cost about \$5,000,000, including site, recently secured, on the Yellowstone Highway, about 4 miles from Casper.

British Columbia

NEW WESTMINSTER—The Triangle Chemical Co. is planning for the establishment of a new local plant for the manufacture of muriatic acid, sulphuric acid, superphosphates and kindred products.

Capital Increases, etc.

THE GAYNER GLASS WORKS, Salem, N. J., has filed notice of increase in capital from \$150,000 to \$500,000.

THE WESTERN PAPER MAKERS' CHEMICAL CO., Kalamazoo, Mich., has increased its capital from \$200,000 to \$1,000,000.

THE SHAMOKIN POWDER CO., Shamokin, Pa., has filed notice of dissolution under state laws.

THE ILLINOIS TERRA COTTA LUMBER CO., Pullman, Ill., manufacturer of burned clay products, has filed notice of dissolution under state laws.

THE CHEMICAL PRODUCTS CO., Detroit, Mich., has filed notice of dissolution under state laws.

New Companies

THE MCKINNEY COTTON OIL CO., McKinney, Tex., has been incorporated with a capital of \$100,000, to manufacture oil products. The incorporators are J. S. Heard and F. B. Pope.

THE LEWES FERTILIZER CO., Lewes, Del., has been incorporated with a capital of \$1,700,000 to manufacture fertilizers, phosphates, etc. The incorporators are Charles D. Murphy, Harrington, Del., and James M. Tunnell, Lewes, Del.

THE DEALERS CO-OPERATIVE OIL CO., Haddonfield, N. J., has been incorporated with a capital of \$125,000 to manufacture oil products. The incorporators are Herman Schreiner, Jr., C. E. Brearley and Edward T. Catlett, Haddonfield.

THE TRINACHIA DRUG & CHEMICAL CORP., with a capital of \$25,000 to manufacture chemicals, chemical byproducts and kindred specialties. The incorporators are G. Porrazzo and C. Firestone, 299 Broadway, New York, N. Y., has been incorporated.

THE REGAL ASBESTOS MINES, INC., New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture asbestos products. The incorporators are E. Hemming, E. A. Barth and A. Pettit. The company is represented by McCole & Reid, 80 Maiden Lane.

THE WARWICK CHEMICAL CO., East Greenwich, R. I., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are Harry A. J. Clarke, Samuel A. Olevson and John J. Clarke, West Greenwich, R. I.

THE COLONIAL OIL CO., Room 734, 208 South LaSalle St., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture oil products. The incorporators are William C. Blean, Raynald A. Whitehead and Furber I. Marshall.

THE KEARNEY FOUNDRY CO., Newark, N. J., has been incorporated with a capital of \$25,000, to manufacture iron and other metal castings. The incorporators are Robert Douglas, William Baskerville and Colin D. Matier. The company is represented by Clyde D. Souter, 31 Clinton St., Newark.

THE SILICA GEL CORP., Garrett Bldg., Baltimore, Md., has been incorporated with a capital of 600,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are Benjamin F. Lovelace, Ernest B. Miller and Walter A. Patrick.

THE ENDICOTT OIL CO., Endicott, N. Y., has been incorporated with a capital of \$150,000, to manufacture oil products. The incorporators are A. H. Burmont, R. B. Hoadley and W. J. Doyle, 78 Laurel Ave., Binghamton, N. Y.

THE FLASHITE CO., 208 South Clark St., Chicago, Ill., has been incorporated with a capital of \$10,000, to manufacture waterproofing compounds, insulating materials, etc. The incorporators are Andrew G. Burt, Jr., William F. Waugh, and Philip H. Newman.

THE TEXAS SHOPE BRICK CO., Dallas, Tex., has been incorporated with a capital of \$75,000, to manufacture brick, tile and

other burned clay products. The incorporators are E. H. Jones, B. K. Howard and J. G. Strawn.

THE LAKE CHAMPION PULP & PAPER CORP., Plattsburgh, N. Y., has been incorporated with a capital of \$200,000, to manufacture pulp and paper products. The principal incorporators are Thomson Douglas, 4 Elk St., Albany, N. Y.

THE PATERSON LEATHER CO., Paterson, N. J., has been incorporated with a capital of \$50,000, to manufacture leather products. The incorporators are Edward F. Murphy, Martin J. Fogarty and Jacob Van Hetloo, 32 Main St.

THE E. L. COOK BRICK CO., Bridgewater, Mass., has been incorporated with a capital of \$100,000, to manufacture brick and other burned clay products. Ernest L. Cook is president, and G. M. Cook, treasurer, both of Bridgewater.

THE BERING-KRAMMERER OIL CO., Long Beach, Cal., has been incorporated with a capital of \$500,000, by R. E. and L. H. Bering and William Krammerer, Long Beach, to manufacture petroleum products. The company is represented by Desmond & Larzelere, attorneys, Long Beach.

THE SPANISH AMERICAN CORK PRODUCTS CO., Westport, Md., has been incorporated with a capital of \$500,000, to manufacture cork specialties, insulation products and affiliated materials. The incorporators are Walter V. Harrison, C. J. Denhard and Philip S. Ball, Westport.

THE PADDOCK PAPER CO., Providence, R. I., has been incorporated with a capital of \$50,000, to manufacture paper products. The incorporators are Stephen D. and Louis N. Paddock and Edward J. Davis, Cranston, R. I.

THE SAN TONE OIL & REFINING CO., San Antonio, Tex., has been incorporated with a capital of \$2,500,000, to manufacture refined oil products. James Kepley is president; and M. A. Arnett, secretary and treasurer, San Antonio.

THE METAL CLEANER CO., Wilmington, N. C., has been incorporated with a capital of \$125,000, to manufacture cleaning compounds and other chemical specialties. Edward Sandlin is president and general manager; and F. B. Markey, secretary and treasurer, Wilmington.

THE PAN-AMERICAN PAPER PRODUCTS, Philadelphia, Pa., has been incorporated with a capital of \$150,000, to manufacture paper specialties. The incorporators are Wells H. Hall, Ira G. and E. H. Ross, Philadelphia. The company is represented by James A. Coady, 914 West St., Wilmington, Del.

THE ECONOMY OIL CO., Taunton, Mass., has been incorporated with a capital of \$25,000, to manufacture oil products. Samuel Cohen is president; and Alexander Glaser, 92 Summer St., treasurer.

THE BRICKSTILE CO., 500 Diversey Ave., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture wax products, tile and other burned clay specialties, and cement materials. The incorporators are H. B. and H. H. Minnick and Ambrose J. Krier.

THE INTERNATIONAL VARNISH & COLOR WORKS, 495 Cortland St., Belleville, N. J., has filed notice of organization to manufacture paints, varnishes, etc. Joseph Bozzol, 312 North Fifteenth St., East Orange, N. J., heads the company.

THE ACME PAPER CO., INC., Boston, Mass., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture paper products. William P. Yanes, is president; and Jacob A. Promboin, 156 Line St., Cambridge, Mass., treasurer.

THE CHATTANOOGA BRICK CO., Chattanooga, Tenn., has been incorporated with a capital of \$50,000, to manufacture brick and other burned clay products. The incorporators are Luze C. Hale, Sr., and Robert E. Winsett, Chattanooga.

THE RIDGEWOOD MFG. CO., Brooklyn, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemicals and kindred products. The incorporators are E. Luca, C. Cavallino, and C. A. Winter, 507 Fifth Ave., New York.

THE PHILIPPINE REFINING CORP., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture refined oil products. The incorporators are C. W. Hamilton, O. C. Sanborn and A. C. Patterson. The company is represented by Larkin, Rathbone and Perry, 80 Broadway.

THE TONKIN FLAKE GRAPHITE CO., INC., New York, N. Y., has been incorporated with a capital of \$150,000, to manufacture graphite products. J. J. Tonkin, Highbridge, N. J., is the principal incorporator.

THE TAR HEEL OIL CO., Greensboro, N. C., has been incorporated with a capital of

\$350,000, to manufacture refined oil products. The incorporators are J. M. Hunt, and W. J. Jones, Greensboro; and W. L. Stamey, High Point, N. C.

THE LIFE SAVER SOAP WORKS OF AMERICA, 10 South LaSalle St., Chicago, Ill., has been chartered under state laws, to manufacture soaps and kindred products. The incorporators are Alexander Gibbons, M. Goodrich and Louis Kaplan.

THE ELITE CHEMICAL CO., 40 Frank St., Providence, R. I., has filed notice of organization to manufacture chemicals and chemical byproducts. John F. Aptt and Foster F. Hocking head the company.

THE DEFENDER OIL CO., Huntington, W. Va., has been incorporated with a capital of \$200,000, to manufacture oil products. The incorporators are C. C. Curtis and G. L. Bremmer, Huntington.

THE HERCULES CORRUGATED BOX CORP., New York, N. Y., has been incorporated with a capital of \$60,000, to manufacture corrugated paper products. The incorporators are J. Breem, B. W. Rod and M. London, 55 Liberty St.

THE BROOKLYN PACKERS BYPRODUCTS CORP., Brooklyn, N. Y., has been incorporated with a capital of \$10,000, to manufacture greases, oil compounds, fertilizers, etc. he incorporators are L. Weill, M. Lehman and N. D. Shapiro, 892 Broadway, Brooklyn.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN PEAT SOCIETY will hold its fifteenth annual convention at the Hotel Commodore, New York City, Sept. 7, 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del. Oct. 18 to 20.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society regular meeting.

Wisdom in Managing an Educational Institution

WHILE we continue to twit our California friends and to assure them that we have already heard of their far-famed climate, they seem to be doing things out there. In fact they have been doing things for several years. Some time ago in talking with one of the most illumined professors of chemistry in the country he expressed a desire to go to California and to visit Berkeley.

"Why?" we asked.

"I should like to observe how GILBERT LEWIS does it," he replied.

Now the school of chemistry at the University of California has so established itself that it needs no encomium from us; but here comes the announcement of the California Institute of Technology that Dr. ROBERT A. MILLIKAN, professor of physics at the University of Chicago, will go permanently to Pasadena to become director of the Norman Bridge Laboratory of Physics at the Institute and chairman of its Executive Council. The presidency of the Institute was offered to him, but—let us quote a few words of rare wisdom from a note on the subject in *Science* of August 12. "The trustees . . . were appreciative of his desire not to be burdened with the administrative duties usually attached to that office and have created a new administrative board to be called the Executive Council, which will combine the usual functions of the president and the executive committee of the board of trustees. It will consist of six members, three trustees and three members of the faculty, viz.: ROBERT A. MILLIKAN, chairman; ARTHUR H. FLEMING, president of the board of trustees; HENRY M. ROBINSON, first vice-president of the board (and president of the First National Bank of Los Angeles); GEORGE E. HALE, director of the Mt. Wilson Observatory; ARTHUR A. NOYES, director of the Gates Chemical Laboratory, and EDWARD C. BARRETT, secretary of the Institute."

How rare, and how sweet to the scientific ear it is to hear that the trustees themselves were mindful of the fact that a great teacher does not want to be burdened with administrative duties! And how reasonable it is, in an establishment that has no ambition to be big in the number of its students, to secure the advantage of his wisdom along with that of Dr. HALE and Dr. NOYES in conjunction with the president, the first vice-president and the secretary of the board to order the affairs of an institute of science!

Liberal provision has been made for the prosecution of research and a joint attack is to be made from the physical and chemical laboratories on "the most fundamental problem of physical science today: that of the constitution of matter and its relation to the phenomena of radiation."

In addition to the advantage of the occasional presence of Professor A. A. MICHELSON of Chicago, Professor H. A. LORENTZ of Leyden will be in residence as lecturer and research associate during two months of the coming winter and Dr. C. G. DARWIN of the University of Cambridge has been appointed professor of mathematical physics for the college year of 1922-23.

We do not want to appear before our readers as too radical or as iconoclastic. We recognize the value of traditions and the merit of maintaining them. But given a student with a mind open to mathematics and an unspoiled curiosity in regard to the unseen causes of things, we venture the opinion that there is more in it for him, somehow, to study among selected students with these masters of science than there would be if he were captain of a football team that is champion of the Pacific Coast, the Rocky Mountains, the Middle West and the Atlantic Seaboard all at once. There is more in it for him than there would be in making the Harvard Crimson fade away to a pale pink, the Yale Blue look almost white and in reducing the Princeton Tiger to a maltese cat on all the fields of sport. Shocking as this may sound, we venture to say it right here, in the open, on the irrevocable printed page.

Now bring along your University Clubs!

The Long, Long Road to Results

ARS longa, vita brevis est. And long, too, are the ways of industry, which is itself an application of the arts. We children of men are crude, very crude, and it takes generations to do what we know should be done and wish to see done. If we look at a railway locomotive with a scientific conscience, we recognize immediately that it is a wretched thief of the heritage of future generations in its voracious wastefulness. A blast furnace is also as much of a destructor as it is a producer. And why should we transport coal on expensive railroads, then on still more expensive trucks, then on trucks again only to get a little of the available energy out of it while we waste the precious lower hydrocarbons that it contains?

We know better but somehow we don't get around to it. On every side we see things done as they should not be done; but the inertia of tradition and the lack of competent leaders inhibit progress. Look at our methods of transporting freight by rail. For example, A wants to deliver to B, who lives a hundred miles away, two tons of a product which he makes. There are no standard containers, everybody uses what he can get. A 5-ton truck carries the two tons of merchandise to the freight shed. There it waits until a car comes along that is going in B's direction

or destined to the place where B wants the goods. Not once in ten thousand times is it possible to put it on the car with the mechanical economy provided by cranes and platform cars. Usually it is banged about by a lot of roustabouts and with innumerable strains and shouts it is shoved through the narrow door of a box car. Stevedore work is required after it is in the car. When the car is wholly or partly filled it is shunted off to wait a convenient train and then it is shunted on again. Arrived at its destination, there is more straining and grunting to get it out of the door, on a platform and under cover. B then receives a postal card that his goods have arrived and he sends a 5-ton truck that may not have to wait more than five or six hours and then it takes more grunts and strains to load it up and to unload it after the truck arrives at his place of business. The time is likely to be a week or ten days for shipment and nobody knows how many men have been banging it about with hooks and eating up its value with time-and-a-half or double for overtime.

Adequate terminals with cranes overhead depositing each parcel of freight from above on a flat car already part of a predestined train, and tarpaulin covers when needed, would take care of the loading and unloading in a small fraction of the time and expense now required. The railroads themselves or a single co-ordinated trucking concern could gather up and deliver freight with a fraction of the expense now involved. Why don't we do these things? Why are we so slow in making advances? The answer is very simple. We lack the men in place to see improvements through.

In many respects the world is bobbing around like a chicken with its head cut off simply because of a lack of leaders.

Mechanical Engineering In Chemical Production

TWO of the articles in this issue have been contributed by mechanical engineers. Although this in itself is not an unusual occurrence, it serves to emphasize the close relations existing between the different branches of the engineering profession. The chemical engineer must rely upon his older brother for much of the mechanics of chemical production. He must be able to draw from the other divisions of engineering as much of their specialized knowledge and experience as will serve to assist him in solving his problems. He must in turn contribute his own experience and expert advice so that all may derive benefit from the common fund of knowledge.

CHRISTIAN KRARUP, who gives us the article on potash recovery, is a mechanical engineer confronted with the thoroughly practical problem of putting the cement mill's byproduct industry on a paying basis. The cement dust must be separated from the volatilized salts as early as possible in the operation or else difficulties arise which prevent the proper application of the fundamental principle of the process. The raw material dust causes trouble for the electrical engineer in charge of the precipitation chamber and later on the separation of the gypsum from the mixture of dust and potash tests the skill of the chemist and chemical engineer. The problem was solved, however, by a combination of simple mechanical operations. Water sprays, which are used to cool the gases before they pass to the electrical

treater, were used to remove the bulk of the dust, and the remainder was separated by gravity precipitation. This simple modification of the process meant the difference between success and failure for the byproduct installation.

The second article is by THOMAS G. ESTEP. He deals with a problem of interest to the operating engineer who is concerned with the measurement of gases. He tells us that engineers are often apt to overlook the necessity for correcting their gas measurements for the water vapor contained in the saturated gases, even though large errors can thus be introduced into their determinations. In most cases the correction for the vapor is greater than the error due either to observation or to the accuracy of the measuring device. All of these devices, such as Pitot tubes, Venturi meters, orifices and throttle disks, measure the gases in terms of velocity as indicated by a measurable differential pressure. To calculate the volume of the gas from its velocity, however, requires a determination of density, and herein lies the difficulty. Since the gas is a mixture of gas and water vapor, either an accurate analytical determination is necessary or the operator must resort to a laborious mathematical process. Professor ESTEP, recognizing the delay that the tedious calculations and physical measurements usually involve, has prepared a set of curves which will materially assist in the calculation where a gas saturated with water vapor is being measured. Knowing the temperature and pressure of the gas at the point of measurement and the specific gravity of the dry gas, the specific gravity of the saturated gas can be read directly from the curves. This value can then be subtracted in the usual velocity formula, from which the volume of the gas can readily be calculated. The procedure for partly saturated gases is also simplified by these graphical determinations.

The mechanical problems referred to in these articles are similar to many which are met in chemical production, and therefore they lie distinctly within the field of chemical engineering. If the chemical engineer is to serve his industry to the fullest extent, he will do well to profit by the experiences of workers in other branches of the engineering profession.

Athletics And Chemistry

IT IS not our habit to discuss or to record intercollegiate or international sports, or sport of any kind except the queen of them all, which is the hunt for knowledge in science. But at the international meet in New York in July there was a sequel to an event which seems interesting from the standpoint of chemistry. The contestants in the one-mile run were STALLARD of Cambridge, IRISH of Cornell, McCULLOCH of Princeton and KENT-HUGHES of Oxford. Our interest is in the first named. He's a tall, lank Englishman, or looks like one, wherever he hails from. He saved his wind without falling behind until they had covered about three-quarters of the course and then with all his might and all his strength forged ahead and won the race by a considerable lead. He conserved his powers until they were needed and then he put everything he had into it.

Of course, there is nothing remarkable in that; every good athlete tries to do it, but it is pleasing to observe.

At about this time the captain of the Oxford-Cam-

bridge team came and took place beside a neighbor during some events in which he was not entered. "That STALLARD is a rum fellow," said he. "He is quiet and rather shy, but good company when you can get him. He has, however, a passion for chemistry, and you can't get him away from his chemistry books. On the way over he would take his exercise and then go back to them all the time. He spent from eight to ten hours a day at them, reading them with gusto like a boy with 'The Three Musketeers.' He lives in chemistry all the time."

This reminded us that Sir ERNEST RUTHERFORD is in Cambridge and so is Sir WILLIAM POPE, and other teachers of great repute and worth; that they have sound traditions in science and mathematics at that university, and that it might be worth while to make note of the name of the athletic student of chemistry: S-T-A-L-L-A-R-D.

Steadier Prices

Mean Business Expansion

THERE can be no doubt that the volume of business transacted will increase as a result of the fairly stable basis the commodity markets have reached, whereas last winter everyone was insisting that business was halted while men waited for prices to decline. It does not follow, of course, that business will resume the swing it appeared to have in 1920. The showing of that year was partly fictitious. Since we lack comprehensive statistics of the volume of business transacted from time to time, we naturally fall back on symptoms, particularly prices. We have since found that in the case of many commodities the high prices ruling in 1920 did not really prove that there was a heavy demand, and the stocks that represented frozen credits toward the close of the year showed that in some instances the supply had been really in excess of the demand, the holders having contrived to conceal the fact. We may indeed reach a stage in the near future of doing a larger volume of business than was done in 1920, while the outrageous prices of that year certainly will not be developed.

The volume of business that is being done now is larger than is commonly assumed. The last report of ton-mileage freight movement on the railroads, for the month of May, shows an increase over the rate in April, and a rate slightly in excess of the rate in the best railroad year before the war, that being the year ended June 30, 1913. The Federal Reserve Board reports that debits to individual accounts at banks in the week ended June 1 were only 17 per cent less than in the corresponding week of 1920, while the week ended June 22 showed a lag behind 1920 of only 14 per cent. These showings are quite different from the common appraisals of the volume of business being done. The reaction to them should be that new light is being thrown on the situation, not that they are things to be explained away. They are plainly of fundamental importance.

Reverting to the statement that commodity prices are now much steadier, the Bureau of Labor Statistics at Washington released its wholesale price statement for July on August 18. This showed an index number (1913 = 100) of 148 for July, the same as had been shown for June. Farm products and "food, etc." increased two points each from June to July, while the other items, which are not weighted as heavily in the total, declined various numbers of points.

The readjustment is either completed for the time being or has reached its final stages, indicated by the fact that no longer are all prices declining. Early in the readjustment a common feeling was that if commodity A had experienced a great decline or had approached its pre-war price, and commodity B had had only a small decline or was still far above its pre-war level, then it was up to commodity B to do a great deal more and it was necessary to wait for the slacker to do his duty. Dr. HURLIN's statistics, commented on in these columns under date of July 27, 1921 (page 135) showed that commodity prices in general declined for about thirty years after 1815 and after 1865. The point is that some commodities can get down easily while others have a hard time of it. The divergences now in advances over 1913 averages shown by different commodities are due largely to that fact. The prices that are high have to be accepted as likely to decline but little from month to month. A basis for doing business is afforded.

Price divergences now are due largely to differences in the character of the costs. Some high costs were shaken out readily. Others yield grudgingly. Such increases in costs as are due to freight rates have not been shaken out at all, for freight rates have not been reduced. We cannot take a fixed relation to 1913 prices and say that each commodity must conform to that relation or be left alone until it does. Indeed, the entire process of deflation may be stopped altogether, for there are some able economists who now argue that we are likely to have a "secondary inflation" for a time.

A Silk Purse

From a Sow's Ear

A FEATURE of the exhibit of Arthur D. Little, Inc., at the coming National Exposition of Chemical Industries, is a silk purse made out of a sow's ear. This hardly belongs to industry in the commercial sense, but it is at once an object lesson and a contribution to philosophy. First there was the sow which "passed on" as the saying is—but into provisions here present in accordance with her genus rather than into the less definitely known Great Beyond. The ears, instead of going into pickle, went into glue and the glue was softened in water, brought almost to the point of precipitation with acetone, then forced through a warm container into a spinneret and through this into a hardening solution of formaldehyde and acetone in a V-tube. It was picked out of the V-tube, reeled, dried, treated to a 40 per cent glycerine bath in which it was also dyed, then reeled and dried again, woven and sewed up—and there is as handsome a silk purse as ever was carried by the gentle abbess of whom CHAUCER sings and who never messed up her wineglass while engaged in the conviviality which now, alas, is denied to us.

As a chemical achievement it was play, mere play; an incident of minor research. Our interest in it is as a contribution to philosophy. This trinket, of which the silk is not even strong or of especially good quality, should serve as a mighty club in argument. The wretched old saw, "You can't make a silk purse out of a sow's ear," has been echoed down the ages, the Bourbon chortle of those who never learn and never forget. Let's hope that it may serve to refute the footless arguments of the ignorant and that it will help to lay those hoary ghosts of the past that jabber against progress. Science can do.

Readers' Views and Comments

Case Hardening and Oxidation of Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—Many events have prevented me from paying the necessary attention to the important paper by Mr. Matsubara on "Chemical Equilibrium Between Iron, Carbon and Oxygen" read before the February meeting of the American Institute of Mining and Metallurgical Engineers and briefly abstracted in your journal Feb. 23, 1921, page 331. I intend to study very carefully the data contained in this paper, and expect to resume my experimental researches in this very interesting field within a few months.

But in the meantime I must say that many points, both in the experimental part and in Mr. Matsubara's conclusions, seem worthy of a closer analysis, and—in some respects—to be open to some criticism.

His reaction chamber consisted of a glazed porcelain tube partly inclosed in an electric furnace, but whose ends projected into the open air. One end, in fact, was water-cooled. After introducing a certain amount of oxide, evacuating and bringing the furnace to the correct temperature, the gas to be charged was forced into the reaction chamber. After the reaction had proceeded "to equilibrium" the gas was drawn off and analyzed.

I will limit my observations to but two of the many points which could be discussed in connection with this experimental work. Mr. Matsubara does not sufficiently explain his manner of deducing equilibrium data in a vessel which is only partly heated to the reaction temperature to be studied and the balance (about one-quarter of its length) cooled by circulating water. Neither do I find any reference to the time required to withdraw the gas contained in the reaction chamber—which gas cannot be in a true physical and chemical equilibrium for the reason stated above.

These points and the many others that could be quoted perhaps have not been explained by the author for the sake of brevity. But in my opinion they require a complete discussion if the experimental results are to be taken as a sure basis of a new theory in open opposition to the results of previous investigators.

In any case, I am absolutely sure that the results of my experiments on the *simultaneous* oxidation and carbonization of iron by the system $C:CO:CO_2$ under sufficient pressure cannot be explained in the way suggested by Mr. Matsubara—namely, that the oxidation may have been caused by an excess of CO_2 being blown into the mass at too high velocity and reaching the metal before being converted by the hot surrounding charcoal into CO . I am fortified in this belief by the knowledge of many hundreds of carbonizations carried out under atmospheric pressure, but in all other respects under exactly identical conditions as those under higher pressure, not one of which has caused the slightest oxidation of the surface of steel imbedded in the charcoal. Neither did an increase in gas velocity twenty times higher cause any oxidation at atmospheric pressure.

Such simultaneous carbonization and oxidation I explained (and for that matter, still explain) on the basis of Schenck's investigations, easily summarized in

the attached diagram showing isothermals for the two systems in question. If conditions are as here represented, it is obvious that at some pressure p , less than Q , hot carbon will tend to hold the CO concentration at S , which will not only protect any iron from the formation of FeO but bring the carbon in austenite up through various stages represented by curves a_1, a_2, a_3 , etc., eventually arriving at a certain carbon concentration (Σ austenite) which is in equilibrium with the same CO concentration as that generated by carbon. On the other hand, any pressure greater than that represented by Q will cause simultaneous oxidation and carbonization.

Mr. Matsubara's diagram shows the iron oxide vertical displaced far to the left so that the two principal curves do not intersect. Therefore his diagram infers that the admitted phenomenon of combined oxidation and carbonization must accomplish itself alternately in two opposite directions. Thus for some time the $CO:CO_2$ mixture which bathes the surface of the iron would act as a carbonizing agent, but could not cause the least oxidation. In the next period of time the $CO:CO_2$ mixture—having in some unexplained manner changed its composition—should act as an oxidizing agent.

Accepting for the moment this situation, it must be clear that in the second period of time the gas, containing a higher percentage of CO_2 , cannot be in equilibrium

ISOTHERMALS SHOWING CONDITIONS EXISTING DURING CARBURIZATION BY CO AND CHARCOAL UNDER PRESSURE

with the carbonized zone produced previously. Necessarily, then, there must be some decarbonization of the outer layers of metal before the oxidation could occur. Such an intermittent process, no matter what the order or number of the alternate periods, would consequently leave an end product which is quite different from those I have observed without exception in pressure carbonizations.

In my own experience the finished samples always

possessed a thick layer, strongly and very uniformly carbonized, in which the carbon content reached its maximum value at the *outer* surface where the metal was in intimate contact with a thick solid crust of iron oxide. In this crust many pieces of charcoal were imbedded, so that the oxide was in close contact with free carbon, a proof that in my experimental conditions the gas mixture was in equilibrium *at the same identical time* with charcoal, iron oxide and the austenite of highest carbon content.

Aside from all these remarks, it must be constantly borne in mind that it has been experimentally proved, independently of any theory by Schenck or other scientist, that at certain temperatures the simultaneous carbonization and oxidation of iron can take place only when the pressure of the C:CO:CO₂ system exceeds a given value. Hence it follows with the same degree of certainty that the curves corresponding to the two reactions must cross each other at that pressure.

Slip Interference Theory of Hardening

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. Jeffries and Mr. Archer must be congratulated on their very interesting and important contribution to the theory of hardening published in your issue for June 15, 1921. The authors have in "slip interference" found a lucky word, which when made comprehensive enough gives a nice and easily remembered explanation of the cause of hardness, especially after defining hardness as resistance to deformation (or slip). If their theory is correct, it should satisfactorily explain all phenomena connected with hardening, and it may be of interest to discuss a few points to see whether the theory will hold when considered from a few other angles.

The authors state in the beginning that metals owe their hardness and strength to interatomic bonds and, further on, that deformation is caused by slip. I cannot find it clearly so stated, but it must be assumed that such slip will occur between atoms and will take place most easily at right angles to the direction where the sum of interatomic bonds is the least.¹ When some outside force is applied which causes slip between the atoms, these take up new positions, each to each, with stronger bonds. They can then better resist an outside force against further displacement. When the temperature is low and the molecular motion is not lively enough, no rearrangement of disorganized atoms will take place and the phenomenon known as cold-working is the result. When the outside force exceeds a certain limit, the interatomic bonds will be broken.

It is generally conceded, as the authors state on page 1059, that a solid solution will be harder or more resistant to slip than the pure solvent. Anybody who has watched the steel melter forging test samples taken from a furnace bath before and after the addition of a small amount of chromium will know that the sample containing chromium will yield less under the same hammer blow. The interatomic bonds when chromium is present in the hot alloy must evidently be stronger than when chromium free. The question may be asked whether this is caused by a network of Cr atoms in a lattice independent of the lattice of Fe atoms and possibly of a different orientation, or whether there are

distinct bonds between Fe and Cr in one lattice in which Cr atoms have replaced Fe atoms.

To my mind, diffusion at high temperatures and in the molten state is readily explained by assuming the solute to be distributed in the molecular state, and there is good reason to believe that cementite dissolves in that way when taken up by iron. This is denied by Jeffries and Archer. When solids dissolve in liquids like water or alcohol, the solution is molecular. Association or disassociation of molecules may occur according to circumstances. When carbon separates from solution in gamma iron, it is in the form of cementite. Furthermore, hydrocarbons are formed when quenched steels are dissolved in acid. Cementite can apparently migrate even below the critical range, since it is known that the cementite particles of sorbite or granular pearlite decrease in number and increase in size, and that even lamellar pearlite can be converted into granular by prolonged heating at 650 deg. C. These are reasons for assuming that cementite dissolves as such and is not dissociated into carbon and iron. It would be interesting to know in detail the author's reasons for not assuming cementite to dissolve as molecules in γ iron.

Jeffries and Bain have found that cold γ iron has a face-centered lattice and that α iron has a body-centered lattice. In this they are in accord with Dr. Westgren.² Dr. Westgren has not yet been able to determine the space lattice for Fe₃C at elevated temperature and whether there is any change in space lattice when dissolving in γ iron.³ It would be most interesting if someone could succeed in doing this, because it might give an idea as to the form of cementite in γ iron. Most probably the space lattice of a crystalline solvent will have a directional influence on the space lattice of a crystalline solute, at least when the latter has some similar atoms, so that in the same crystal γ iron and cementite will have space lattices of the same general nature. The bonds between atoms in dissolved molecules will be stronger than between atoms in the solvent, thus the mass is made harder.

Like Dr. Westgren, they find that martensite consists mainly of alpha iron, which is in agreement with other known facts, but there is still the possibility that some γ iron is left in quantities insufficient to give interference lines in their photograms.

From remarks and the illustrations on page 1062 it appears that Jeffries and Archer consider it necessary that Fe₃C particles must have reached a relatively large critical size, greater than a molecule, to give greatest hardness to the steel. They state, on the other hand, on page 1065, quoting evidence, that cementite cannot be detected in martensite and, further on, that carbon must be in solution. If cementite should act as keys on cleavage planes in the way the authors apparently explain it, the cementite must have separated out of solution but might still exist as submicroscopic agglomerates of Fe₃C molecules.

The investigation of Andrews, Rippon, and Mills⁴ shows clearly that cementite has not separated from

³ Editor's Note: In a paper read before the British Iron and Steel Institute, May, 1921, meeting, Dr. Westgren gave results on hot and cold iron wires as follows:

Condition	Crystal Form	Length of Edge in Angstroms
Pure iron at room temperature	Body-centered cube	2.85
Pure iron at 815 deg. C. (beta)	Body-centered cube	2.92
Pure iron at 1,000 deg. C. (gamma)	Face-centered cube	3.60
Cold 25 per cent nickel steel	Face-centered cube	3.58
Cold 12 per cent manganese steel	Face-centered cube	3.61

¹Compare the cleavage in graphite.

martensite as such. Andrews shows also that there is an increase in volume of γ iron when Fe_3C goes into solution; further, that a dissociation of carbide molecules is probable in steels with higher carbon contents when heated to high temperatures. The carbide expansion found by Andrews is nearly equal to the increase in volume of martensite over annealed steel. Austenite, on the other hand, has a smaller specific volume, and we know that cold-worked steel has a larger volume than annealed steel. It seems to the writer that these facts, to which the authors have made no mention, are of importance in determining the condition of the carbon in heat-treated steel.

It would be interesting to know whether there is not some slight change of volume in the aging and in the annealing of duralumin.

The increase in volume of α cold-worked steel is evidently due to slips having taken place. Now when γ

FIG. 1. DECREASE IN DIAMETER OF HARDENED STEEL BALLS WITH INCREASING DRAWING TEMPERATURES

iron transforms into α iron an increase in volume also takes place, but the transformation in cooling does not take place instantaneously throughout the whole mass. Crystallization of α iron starts on cleavage planes and grain boundaries of the γ grain and the first α iron formed will tend to rid itself of the cementite present, but like in any other rapid crystallization, it succeeds but imperfectly. At the same time the volume changes attending transformation will cause mechanical work to be done on the surrounding metal, causing slippage and further increase in volume.

Gradual change in carbon content of martensite needles is easily seen by etching, especially in highly drawn nickel steels.

Portevin⁵ showed that martensite forms below 300 deg. C. and that it takes time to form. An experience similar to the aging of duralumin can be cited. When hacksaw blades are hardened they can be straightened and set when they are no cooler than 100 deg. C. immediately after being withdrawn from the quenching bath, but if they have been cooled to room temperature and reheated 100 deg. C. or more, they cannot be straightened. Thus there is evidently some internal slipping going on in the steel immediately after quenching.

Andrews shows that on drawing hardened steels there is a cementite separation with decrease in volume at about 100 to 150 deg. C. and a transformation of γ to α iron at about 400 deg. (shown by change in electric and magnetic resistance), but with a further decrease in volume which must be explained by healing the slip

planes and closing of voids. The attached curve (Fig. 1) made by Mr. Wright of the Atlas Ball Works, showing decrease in diameter of hardened balls by drawing to different temperatures, may be of interest in this connection. We have also found that simple storage at room temperature for a considerable time is sufficient to decrease a ball-diameter measurably. Andrews' investigation seems to indicate the presence of a small amount of γ iron even after hardening straight carbon steel, where he (Andrews) does not believe it is present, and Dr. Westgren also believes that his photograms show presence of γ iron in hardened steel.

Is it not reasonable therefore to conclude that in hardened steel, cementite is in solution in the traces of gamma iron left after most of the α iron has formed. The Fe_3C molecules are still in solution, perhaps polymerized, and, with the γ iron, forming a kind of gel in the iron, but not separated as crystals of cementite. In such form the dissolved cementite molecules may well be considered as keys on the slippage planes of the iron.

Portevin showed that troostite forms at about 600 deg. C. and it is agreed that free cementite is then separated.

It seems clear that the crystallization power of ferrite and cementite, influenced in turn by the presence of other solutes in iron, will have some influence on the final product.

When martensite is formed from solid solution there is doubtless a grain refinement due to the formation of

FIG. 2. SECONDARY FERRITE IN CHROMIUM STEEL. $\times 1,000$.

the many new particles of α iron, but it should not be concluded directly that the hardness of the mass will be in inverse proportion to the size of such particles (which latter probably will have some relation to the size of the γ grain from which they are formed). McCance⁶ shows little variation in Brinell hardness by increasing the quenching temperature, even though a coarser martensite is thereby produced.

How would the theory of Jeffries and Archer explain the formation of Hultgren's secondary ferrite in tungsten steel⁷ and a similar phenomenon illustrated in Fig. 2 found sometimes in chromium steel? How would they explain the presence of internal stresses in hardened steels?

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, Italy, Aug. 1, 1921.

JULY was characterized by the return of orders on the Italian market, brought more through the fear of future increase in price, caused by a higher foreign exchange, than through the weak industrial demand. Such orders were principally for the commoner products and brought up prices of these, but they did not stop a further fall in price in the case of other products, despite the higher importation taxes arranged, the full force of which was felt the first of the month.

NEW IMPORTATION TARIFFS ON CHEMICALS

The new importation tariffs are as follows: Silicate of soda and silicate of potash, in solution, 10 lire gold per ton; silicate of soda, solid, 25 lire gold; hypochlorite of potash and hypochlorite of soda, 40 lire gold; hypochlorite of lime, 20 lire gold; bicarbonate of soda, 30 lire gold; beet-root ashes, exempted; vegetable ashes, exempted; crystallized carbonate of soda, 10 lire gold; calcined carbonate of soda, 30 lire gold; carbonate of potash, 20 lire gold; carbonate of lead, 80 lire gold; carbonate of ammonia, 120 lire gold; carbonate of barium, 40 lire gold; carbonate of magnesia, 25 lire gold; ammonia, compressed, 120 lire gold; ammonia in solution, 50 lire gold; solid caustic soda, 30 lire gold; liquid caustic soda, 20 lire gold; caustic potash, 30 lire gold.

REDUCTIONS IN IMPORTATIONS

The first four months of this year saw quite a general reduction in importations and exportations. The following were the values of some of the imported commodities: Benzine, 11,000,000 lire; petroleum, 12,000,000 lire; carbonate of soda, 13,000,000 lire; paraffine, 15,000,000 lire; explosives, 11,000,000 lire. The values of some of the exported products were: Citrate of lime, 30,000,000 lire; citric acid, 10,000,000 lire; sulphur, 15,000,000 lire; raw tartar, 7,000,000 lire; sumac, 7,000,000 lire.

SUGAR IMPORTATIONS

In the year 1920 the sugar importations reached only 11,374 tons in the case of the finer product, against 73,465 tons in 1919 and 29,713 tons in 1918; and only 1 ton in 1920 in the case of the second class product. The total importation of the first class sugar can be subdivided as follows: United States, 6,635 tons; Japan, 430 tons; Egypt, 326 tons; Argentina, 11 tons; Brazil, 241 tons; Cuba, 179 tons; Dutch East Indies, 1,575 tons; France, 1,523 tons.

HYDRO-ELECTRIC DEVELOPMENT IN ITALY

Italy developed with great energy its hydro-electric plants during the time of the war to meet as far as possible the demand for combustibles of all sorts, and at the end of 1915 as many as 329 plants were at work, with a total capacity of 835,000 hp. After 1915 fifty-eight other plants were constructed, producing additional 217,000 hp., and at present fifty-seven new plants, representing more than 599,000 hp., are under construction. For this reason Italy will soon have hydro-electric plants capable of producing about one million and a half horsepower. Fifty-nine mountain lakes will soon be completed for the above plants, having a capacity of 225,000,000 cu.m. Of these, seven have a total capacity of 10,000,000 to 40,000,000 cu.m. In addition

seventeen other reservoirs with a capacity of 701,000,000 cu.m. are now under construction. Among them is the enormous Tirso reservoir in the Isle of Sardinia, which will have a capacity when finished of more than 400,000,000 cu.m.

PRODUCTION, IMPORTATION AND EXPORTATION OF SUPERPHOSPHATES

The production of bone superphosphates was greatly reduced through the war, falling from 924,736 tons in 1914 to 911,190 tons in 1915, 867,690 tons in 1916, 489,000 tons in 1917 and 480,000 tons in 1918. The importation also showed a marked decrease, being reduced from 38,249 tons in 1914 to 13,765 tons in 1915, 2,040 tons in 1916, ceasing altogether in 1917, and again reaching only 164 tons in 1918 and little more in 1919. In 1920 the total imports of all fertilizers reached 5,353 tons (leaving out Thomas slag). The exportations of bone superphosphates were 19,981 tons in 1914, 12,925 tons in 1915, 4,482 tons in 1916, 895 tons in 1917 and 6 tons in 1918, being stopped altogether after this. In 1914, 943,004 tons of bone superphosphates were available for agricultural purposes as against 912,030 tons in 1915, 865,248 tons in 1916, 488,105 tons in 1917 and 480,158 tons in 1918.

Up to the end of 1918 no production of mineral superphosphates was recorded. The importation was 513,998 tons in 1914, 456,901 tons in 1915, 434,713 tons in 1916, 230,150 tons in 1917 and 231,679 tons in 1918. The exportations of mineral superphosphates reached 8,560 tons in 1914, 1,805 tons in 1916, being stopped after this altogether. The mineral superphosphates in stock were 505,429 tons in 1914, 455,096 tons in 1915, 434,712 tons in 1916, 230,159 tons in 1917, and 231,078 tons in 1918.

These great reductions in the available stock of superphosphates impoverished the Italian soil, and production was reduced considerably and has not yet reached the proportions realized before the war.

ESSENTIAL OILS AND CAMPHOR IN ITALY

Italy exports yearly about 30,000,000 lire of essence of flowers and aromatic plants. Among the essences produced in largest quantity is that of the flowers of the lavender plant, of which several million kilos are prepared yearly, and the price has risen during ten years from 20 to 150 lire per kilo. The essence of mint, which is produced in Piedmont and to a larger extent in the provinces of Turin and Cuneo, where the plant can be cultivated with a very high yield on account of the special nature of the ground, is exported to France and to England. Thyme oil has so far been produced principally in Sardinia, and more than 100,000 kilos of essence or oil of bergamot (which is largely employed in the preparation of eau de cologne) is produced, especially in the province of Reggio Calabria. The essences of rosemary, of anis, of orange flowers, etc., are also produced, but so far not in very large quantities.

Italy is in a position to produce natural camphor, as the camphor laurel is cultivated fairly easily at Naples and thereabout, at Caserta, at Rome, at Pisa, at Florence, on the Riviera and on Lake Maggiore. For the extraction of the camphor the green and dry leaves and the small branches of camphor laurel are employed. The yield in these portions of the plant is more than the yield of any foreign plant, but the yield in the roots, branches and trunk of the Italian laurel is much below that of foreign plants, especially the Japanese variety.

The Successful Recovery of Potash as a Byproduct From Cement Kilns

Difficulties Encountered in Placing Byproduct Industry on a Paying Financial Basis and a Description of a Successful Plant in Which the Cement Dust Is Separated From the Potash by Spray Washers Prior to the Electrical Precipitation

By CHRISTIAN KRARUP

MECHANICAL ENGINEER, SANTA CRUZ PORTLAND CEMENT CO.

THE comparatively small quantity of potassium salts volatilized from the raw material in rotary cement kilns and subsequently discharged into the atmosphere with the dust in the waste gases, suddenly came into prominence at the time the recent war cut off the usual supplies of this valuable material. The recovery of potash from the waste gases was undertaken by several cement companies throughout the United States, but in view of the fact that many of these attempts have met with failure, it is believed that the following account of a successful plant will be of interest. Rather than to give a detailed description of the plant, however, which admittedly may be considerably simplified and improved upon, it is the purpose of this article to point out the various problems encountered and to state the line of reasoning and the assumptions forming the basis for the design of the plant. It is believed that the information it is intended to convey will in that form be made more useful as an aid in the design and construction of future plants.

The quantity of potash available for collection varies at the different plants according to the raw materials used in the manufacture of the cement. It is stated that the average quantity volatilized at the plants in the United States is somewhat in excess of 2 lb. of actual potash (K_2O) per barrel of cement manufactured, although at several plants as much as 4 lb. is volatilized. The recovered salts, consisting mostly of potassium sulphate, with some sodium sulphate, have been used principally as an ingredient in mixed fertilizers, but as these are made up according to definite specifications, the low and irregular potash content in the recovered product makes it somewhat undesirable for this purpose. Valuable as potash is as a fertilizer, it has, of course, no value whatever as a commodity unless placed on the market in a satisfactory commercial form. To realize better financial returns from the recovered potash, several companies therefore undertook to refine the product by leaching the salt from the dust and evaporating the solution to obtain the salt in a concentrated form. This process, however, had considerable trouble and expense attached to it and also resulted in some loss of potash, which made still more pertinent the question as to whether the industry would be able to survive at all, should the price of potash fall to the pre-war level.

GYPSUM CAUSES DIFFICULTIES

That such a simple refining process should present any unusual difficulties may not be immediately apparent to the reader, but the elimination of gypsum has proved to be a serious stumbling block in connection with the recovery of potash from cement kilns. Many schemes, proposed and tried, would in practice have

worked perfectly, if gypsum had not the apparent habit of always crystallizing out where it is not wanted. The gypsum is formed in abundance, because an excess of SO_2 , over that required to form potassium sulphate and sodium sulphate, is generally present in the gases, and if this excess has not all been combined with the lime in the dust to form gypsum, that remaining may be relied upon to expend itself in corroding metals or doing some other equal damage. Aside from the fact that to remove gypsum from the interior of pumps, pipe lines and filters involves considerable expense, the main objectionable feature in connection with gypsum is that it will combine with the potassium sulphate to form a "double salt," which is soluble only in very dilute solution. To separate any appreciable portion of this salt from the dust, it is necessary to use a large quantity of wash water, and this in turn increases the evaporation cost. Under certain conditions a very considerable portion of the potash is tied up in the dust in the form of this double salt and is therefore lost, unless it can be returned to the kiln to be re-volatilized. However, this procedure invariably results in a portion of the salt being crowded into the cement clinker or lost through other channels.

These are the principal reasons why the potash byproduct industry in connection with cement manufacture did not materialize as rapidly as might have been expected. The difficulties met with in connection with gypsum, no doubt, directly or indirectly, are responsible for the fact that the recovery has been abandoned by several companies that were already established in the business. The nature of the difficulties are such that no remedy apparently is possible as long as water is used in the process of separating the salt from the dust and on the other hand, no other course would seem to be left open, once the two are collected together in the mixed condition.

CLASSIFICATION OF DUST AND FUME PARTICLES

Obviously the aim should be to collect each separately, as far as it is possible to do so. The dust and the salt are both present in the gases in the form of minute particles in suspension and are already apparently hopelessly mixed before leaving the kiln, but as the individual particles do not touch one another while in suspension in the gas, it is still possible, if the proper means are employed, to effect a classification of the particles before the collection is made.

It is, of course, essential that this classification should be carried out while the particles are still in suspension, because, if they are collected first and therefore brought in actual contact with one another, no mechanical means are then available for separating them to a

sufficient degree to permit a proper classification being made. This may be explained as being due to the fact that the power of cohesion, and that of adhesion as well, of particles of such extreme fineness is much greater than the weight of the particles themselves, which condition makes it impractical by mechanical means to dislodge individual particles, after they have attached themselves to other particles or objects.

It is of course necessary that the means employed for classifying the particles should recognize the difference in the physical characteristics of the dust and the salt. As the specific gravity of both substances is nearly the same, a difference in the size of the particles must be relied upon to accomplish the desired results. That there is a decided difference in the size of the dust and salt fume particles can readily be detected in a strong light, even with the naked eye. Individual dust particles may be distinguished floating in the gas, while individual fume particles cannot be singled out in the same manner, and their presence can only be recognized by the foggy appearance of the gas.

This difference in their physical characteristics is not surprising, when it is remembered how each is produced. The salt, being volatilized in the kiln, passes through the vapor state, in which condition it becomes diffused into a large quantity of gas; this vapor is condensed into a fog consisting of minute particles of salt in the liquid state, which subsequently change to the solid state, as soon as the temperature becomes low enough. Particles produced in that manner should naturally be expected to be very much smaller in size than the raw material dust particles, which have been produced by a grinding process.

The salt fog behaves very much like the ordinary fog, produced by water vapor in the atmosphere, which does not exhibit any tendency to settle due to the force of gravity, or at least, if such a tendency is present, it is so small as to be negligible; nor do the individual particles of their own accord tend to agglomerate to form bodies of such size that would be expected to settle. The dust on the other hand, it has been found, is acted upon sufficiently by the force of gravity to cause it to precipitate, if it is given the proper opportunity.

DETERMINING THE METHOD OF CLASSIFYING

It is not within the scope of this article to discuss the nature of the forces that cause the fume to act in a manner similar to that of a vapor, although it is composed of solid particles instead, but it is the purpose to bring out clearly that a difference between the dust and the fume does actually exist. While the fume will not settle appreciably by the force of gravity, it will, on the other hand, not stay indefinitely suspended in the gas, but must eventually precipitate upon any surface with which the gas is brought in contact. It is possible to carry out the classification in such a manner that practically no dust will be carried over into the salt, but it is not possible to prevent a certain quantity of the salt from being precipitated with the dust, because the dust particles originating in that part of the kiln where the potash salt is volatilized are surrounded by the salt vapor while suspended in the gas and some of this vapor is condensed upon the dust particles as a nucleus and is therefore firmly attached thereto.

The quantity of salt thus adhering to the dust is probably further increased in amount by the collection of solid fume particles on the surface. As the salt collected with the dust can not be made available for the

market except by bringing it into solution or by returning it to the kiln to be re-volatilized, it is desirable that the quantity, thus caught with the dust, should be held at a minimum. For that reason, the dust should be removed from the gas at the earliest possible moment, and it is necessary to use discrimination in the selection of the method to be used for the purpose.

The method employed must be efficient enough to prevent any large quantity of the dust from being carried over into the salt, and yet, at the same time, not precipitate an excessive amount of the salt into the dust. A solution to this problem has been successfully worked out at the plant of the Santa Cruz Portland Cement Co. at Davenport, California. This company is operating a potash-recovery plant that is of a high efficiency and simple in operation. A high grade product is recovered, containing about 33 per cent of K_2O as potassium sulphate, and the recovered salt is remarkably uniform in quality, seldom varying more than 1 or 2 per cent in its potash content. Each kiln is provided with a separate recovery unit and 10 such units are at present in operation. The daily production of potassium salts is 10 to 12 tons.

SEPARATING THE DUST BEFORE RECOVERING THE SALTS

For the recovery of the salts, the gases are first cooled with water sprays, which also incidentally remove the greater part of the dust; the portion not removed in that manner is then subjected to gravity precipitation and finally the salts are collected by electrical precipitation. The dust precipitated by gravity is returned to the kiln, but that caught by the sprays and therefore contained in water in the form of a thin slurry is conveyed by gravity to a Dorr thickener, where the solids are settled to the bottom and drawn off as a thick slurry. This slurry is filtered on Oliver continuous filters and the cake formed by this operation is dried in a rotary drier. The dried cake or dust is returned to the kiln along with the regular feed of raw material, of which it forms a part. The benefit derived from the return of this dust to the kiln is due partly to its value as raw material, but mostly to the fact that it contains a much higher percentage of potash than the original raw material. The quantity of dust collected in 24 hr. per kiln is about 6 tons and in this dust is the salt which is unavoidably caught along with the dust. This amounts to about 15 per cent of all that is volatilized. The clear liquor from the Dorr thickener is re-circulated through the sprays by a single stage centrifugal pump, which supplies a pressure of about 30 lb. per sq.in. at the spray nozzles.

As the chief interest in the recovery process is centered in the treatment of the gases for the collection of the salts, a detailed description of the auxiliary equipment is not attempted, inasmuch as this part of the plant has no direct bearing upon the results obtained in the recovery of the salts.

The recovery plant was originally designed for the recovery of the salts by the wet process and was operated successfully as such up to the latter part of the year 1919, at which time it was remodeled to meet the requirements for the collection of the dry salts direct from the gases. In remodeling the plant, many desired features in connection with the dry process have not as yet been applied. It is contemplated to eliminate the expense connected with the filtering and drying process by feeding the thick slurry from the Dorr thickener direct to the individual kilns. In no case, however, have

these deficiencies interfered with the proper application of the fundamental principle of the process, which had already been recognized and incorporated in the original installation, namely: "that of separating the raw material dust from the gases before the collection for the salts is made."

COOLING THE GASES

As the dry process of cement manufacture is in use at the Santa Cruz plant, the temperature of the waste gases is high, being about 750 deg. C. This makes it imperative to cool the gases as the first operation, because such a high temperature could not be handled through the recovery plant, on account of the deteriorating effect on the structures, which are of reinforced concrete and steel. It is also advantageous to cool the gases to a low temperature, as it greatly improves the efficiency of collection in the electrical treater.

Water sprays are used to cool the gases. As it is not desired to put the salt fume into solution, the spraying is limited to such an amount as will not completely saturate the gas with water vapor. The temperature may safely be lowered to 100 deg. C., which leaves a sufficient margin over the saturation temperature to insure that the salt fume will remain in the dry state in which it left the kiln. About 75 gal. of water is sprayed per minute and of this about 20 gal. is evaporated and carried off with the gas.

The gases from the kiln are taken from the top of the stack, which is cut off at a point about 40 ft. above the base. In taking the gas at the top, instead of near the base, an advantage is derived from the fact that no dampers are required to control the flow of the gases, which may, at will, be discharged directly to the atmosphere or be drawn through the recovery plant by simply applying the suction of a fan. This arrangement leaves the kiln and its stack a complete unit independent of the recovery plant and permits of its operation with the least interference. The arrangement also tends to increase the safety in operation, as the stack is always open and ready to discharge the gas to the atmosphere in any emergency.

SPRAY WASH TOWER

About 35,000 cu.ft. per min. of gas enters a spray wash tower at the top, at which point the water sprays are also located. The tower is 6 ft. by 10 ft. inside in plan and 21 ft. high. At each 7-ft. level, a shelf projects part way across, leaving openings 4 ft. by 6 ft. at alternate sides of the tower for the gases to pass through.

The efficiency of the water sprays in gathering up these extremely fine dust particles would seem to depend entirely upon to what extent the water sprays are forced to take a different path from the gas and upon the velocity with which the drops of water are made to plow their way through the gas, it being assumed that the dust particle is caught by reason of the fact that it has appreciable size and weight and can not, therefore, get out of the path of the water drops fast enough, whereas the fume particles would veer off with the gas, due to their insignificant size and weight. For the same reason it would seem that fine atomization of the water is not desirable for the purpose of removing the dust, as the fine water particles would travel along with the gases, the same as the dust, and could not be thrown out by any zig-zag arrangement. The high efficiency as a dust collector obtained by this tower, considering the

large volume of gas handled and the comparatively small quantity of water used by the sprays, must be attributed to its small size, with the consequent high velocity of the gas through the tower, combined with the particular arrangement as outlined.

The gypsum crystallizing out on the walls of this tower must be removed at intervals of about 6 weeks. To facilitate this work, the floors, installed primarily for the purpose of giving the gas a zig-zag course, answer admirably as working platforms. Gypsum also crystallizes out in the pump and pipe lines as well as in the spray nozzles of the circulating spray system. The nozzles are removed daily and sand-blasted clean; the pump and pipe line require cleaning about every 6 to 8 weeks. The circulating spray system is installed in duplicate in order to allow time to remove the gypsum without interruption in the operation of the recovery plant.

DUST SETTLING CHAMBER

The efficiency of collection by the sprays can not be depended upon to remain constant at all times, on account of the variable condition of the nozzles, and therefore a supplemental gravity precipitation of the dust is resorted to, in order to control the quantity of dust escaping to the electrical treater. With the sprays in proper working order, about 95 per cent of the dust is removed from the gases in the spray tower, which leaves only a small quantity to be precipitated by gravity; the important object is not so much to remove this small amount of dust as it is to insure uniformity in the quality of the recovered product.

The chamber in which the dust is precipitated is 13 ft. wide by 30 ft. long by 7 ft. high and is located directly beneath the electrical treater chamber, from which it is separated by a floor having openings along the outer walls for the passage of the gas. The openings are of such size as to insure uniform distribution of the gas over the entire chamber. The gases from the spray tower enter this chamber through a large opening in one end, and as they enter they are passed toward the center of the chamber and from there divided and drawn to each side through the openings communicating with the treater chamber. The velocity of the gases is in that manner reduced without turbulence, thus affording excellent opportunity for the small amount of dust still present in the gases to precipitate to the floor. It has been demonstrated by the operation of this chamber that it is possible to settle out the very light and flocculent dust, without resorting to the use of dust-settling flues of prohibitive length and cross sectional area.

ELECTRICAL PRECIPITATION CHAMBER

The electrical treater is of chief interest in the entire installation inasmuch as it is the apparatus by which the salt fume is collected, but it is also of particular interest on account of its many unusual features. In the design of this treater, several distinct departures have been made from the usual types, described from time to time in the various publications. It will be observed from Fig. 1 that the treater is of the plate type, although the plates can not be directly seen, as they are covered with precipitated salts. The treater chamber is 13 ft. wide by about 34 ft. long. On each side of the chamber are benches or shelves above the floor; these are for the purpose of preventing the collected salt, as it drops from the treater to the floor, from passing through the openings into the dust settling

FIG. 1. INTERIOR VIEW OF PRECIPITATION CHAMBER SHOWING THE ELECTRICAL TREATER OVERHEAD

chamber below. The rectangular openings through which the gases enter this chamber are located immediately beneath the shelves. The gases in passing through the treater are distributed uniformly over the entire area by reason of the control obtained through the restricted openings left between the angle irons, which are riveted to the upper edge of the treater plates. These angle irons also serve to stiffen the plates and to keep them in alignment. The plates are suspended from cross beams on top of the treater and are bolted to these through the angle irons.

The outstanding feature of this treater is the large area employed in the collecting field for the gases to pass through. The velocity of the gas is therefore very low, less than 1 ft. per sec.; this permits of the salts, which have been precipitated by the treater, to drop to the floor against the gas current. In the customary types of pipe or plate treaters, it has usually been one of the objects to economize in the floor space occupied. As a result of this, the gas velocity through the precipitating field has been correspondingly high, which necessitated using long pipes or wide plates, as the case may be, in order to obtain good efficiency of collection.

A treater of this type, with pipes 13 ft. long, was experimented with, but did not prove entirely satisfactory, mostly because severe arcing interfered with precipitation and required too much attention on the part of the operator. It was found that these arcs were usually started by some of the deposited salt breaking away from the collecting surface, and as this salt was falling down through the pipe, an electrical disturbance was created that frequently resulted in the circuit-breaker "kicking out." This trouble was aggravated by the comparatively high velocity of the gas up through the pipes, and by the height of the pipe treater, which unduly delayed the salts in falling clear of the electrical field. To overcome these difficulties, the treater now in use at the plant was developed.

The plates in this treater are only 18 in. wide in

the direction of the flow of the gases, which therefore gives a rather narrow field for precipitation, but this is made up for by the large area employed. The treater is 12 ft. wide by 30 ft. long over the plates, and the plates are spaced 6 in. apart. Instead of suspending the electrode wires in the usual vertical position with the necessary weights at the lower end to keep them tight, the wires in this treater are suspended horizontally. By this arrangement the space underneath the treater is left entirely clear, with no obstructions on which the salts can accumulate and thereby invite trouble. The wires, which are two high and spaced 8 in. apart vertically, are strung from bus-bars, rigidly supported by insulators at each end of the chamber. No special provisions are made to take up any slack in the wires due to the expansion from heat, as the elasticity in the wire is sufficient to allow for this. In the middle of the span of the wires is suspended a light grid, which serves

FIG. 2. VIEW OF POWERHOUSE SHOWING CONTROL OF MOTOR-GENERATOR SETS AND TREATERS

to steady the wires and is for that purpose prevented from swinging by diagonal wires running to the bus-bars. This arrangement is plainly seen in the view in Fig. 1.

An iron pipe frame may also be seen directly underneath the grid. This frame supports a small air hammer of a very simple construction, which is used for the purpose of stripping off any salts, that have been precipitated on the wires, by delivering a succession of light blows on the grid. The air hammer automatically withdraws, when not in use, so as to leave the necessary air gap, to avoid arcing from the grid. The air hammer, or some other similar device for vibrating the wires, is an essential part of the treater, since, without adequate cleaning, the wires become unevenly coated with salts, which will form in lumps the size of a fist. These distort the electrical field around the wire with a consequent falling off in the efficiency, besides making operation difficult on account of arcing. The wires are cleaned once an hour by the simple operation of turning on compressed air for a few seconds, which is done by the operator in the power house. (See Fig. 2.) No rapping device is used on the plates, as the salts precipitated on these, of their own accord, drop off during operation, when a certain thickness of deposit is reached. The voltage used on the treater is from 40,000 to 45,000 volts. The efficiency of collection is 75 to 80 per cent.

The salts, dropping to the floor in the treater chamber, are conveyed by a scraper conveyor to one end, where they are discharged through a set of slow moving rolls, directly into sacks. These rolls reduce the salts in bulk to about one-quarter. The salts as collected on the floor are very light, weighing only about 10 lb. to the cu.ft., but after they have been pressed into flakes by these rolls, the weight per cu.ft. is increased to about 40 lb., which makes it possible in shipping to load the cars to capacity weight. These rolls answer the double purpose of compressing the salts and at the same time discharge them to the outside of the chamber against a static pressure of the atmosphere of about $1\frac{1}{4}$ in. of water over the gas pressure in the chamber. This difference in pressure is due to the suction produced by the fan drawing the gases through the plant.

The total power consumption for the recovery plant is about 40 hp. per unit, of which one half is consumed by the motor generator set for the electrical treater. The labor required on each shift to operate the plant consists of: one man to operate the 10 motor-generator sets and treaters; one man to operate the fans and circulating spray system (this man is assisted by another on the day shift only, in miscellaneous routine work) and one man to attend to the rolls and to weigh and tie the sacks of salts. Other labor used periodically to clean out the spray tower is about equivalent to one man employed continuously. The men engaged in filtering and drying the cake or dust are not included in this, as these operations should, without difficulty, be eliminated. It is of course possible to make even greater economy in the labor required by making the necessary provisions. This is a most encouraging feature—viz., that the limit of possibilities in economy have not been reached.

The use of waste-heat boilers to cool the gases instead of sprays would no doubt work in to good advantage, although the sprays should not be entirely eliminated, on account of the better results obtained on the treater by their use, and also because they tend to increase the safety in operation, by forming a barrier through which the flame from the kiln can not propagate to ignite com-

bustible gas, that may be present in the large chambers. The electrical equipment for supplying the high voltage current for the treaters is standard apparatus supplied by the Westinghouse Electric and Manufacturing Co., according to specifications furnished by the Western Precipitation Co. of Los Angeles, California. The treater and all other features in connection with the plant have been worked out at the works.

The responsibility for carrying the problems through to a successful solution rests with: George T. Cameron, president of the company; F. H. Davis, works manager; Fred Davis, superintendent; L. T. Bachman, chief chemist; E. W. Rice, chemist; and the writer, as mechanical engineer.

The Electrolytic Reproduction of Engraved Printing Plates*

BY WILLIAM BLUM† AND THOMAS F. SLATTERY‡

IN 1918 and 1919 the printing requirements of the Bureau of Engraving and Printing increased greatly owing to the large issues of bonds and other securities and to the increased demand for currency. In consequence it was found difficult to prepare the required number of printing plates by the mechanical transfer process, which was previously used entirely for this purpose. When electrolytic methods of reproducing these plates were first investigated it was found that although accurate reproductions could be thus obtained, plates which were similar to the ordinary electrotypes or even plates consisting entirely of electrodeposited copper did not possess sufficient strength to withstand the pressures used in plate printing. While conducting experiments in this connection, George U. Rose, Jr., chief of the engraving division of the Bureau of Engraving and Printing, discovered that by the deposition of alternate layers of nickel and copper it was possible to produce plates having the strength necessary for the purpose. This process of depositing alternate layers of copper and nickel, which has been patented by Mr. Rose, is the basis of the method now used in the new electrolytic plant of the Bureau of Engraving and Printing.

The more rigid requirements of plates to be used in "plate" or "intaglio" printing arise from the fact that in this process the designs (which are all below the plane surface of the plate) are filled with ink, and in order to cause the paper to pick up this ink considerable pressure is required. On the other hand, in using ordinary printing plates (upon which the characters are in relief) the lightest possible pressure is used between the paper and the type. Because of the greater pressure required in using engraved plates there is a tendency for these plates to curve in use unless they are sufficiently rigid to retain their form. Another special requirement for plate printing is that the surface shall have the greatest possible resistance to abrasion, as after each impression the plate is inked, rubbed with a mechanical wiper, and polished by hand, all of which operations exert more wear upon the plate than does the actual printing process.

The experimental work conducted at the Bureau of Standards toward the development of this process

*Abstract of address delivered before the American Electroplaters' Society, July 1, 1921.

†Chemist, U. S. Bureau of Standards.

upon a commercial scale consisted therefore in the determination of the best methods for securing (a) accurate reproduction, (b) a durable printing surface, and (c) the necessary rigidity.

ELECTRODEPOSITION OF MOLD OR ALTO PLATE

For the accurate reproduction of engraved printing plates it was found to be most satisfactory to prepare by electrodeposition a metal mold or negative of the original plate, rather than to attempt to take an impression in lead or wax, as in the ordinary electrotyping process. As upon this metal mold the designs are in relief, this plate has been designated as an "alto." One advantage of producing the altos by electrodeposition is that any change in dimensions such as might occur in wax or lead molding is avoided.

For the production of such an alto from a steel plate the latter is first thoroughly cleaned and is then brushed with graphite in order to permit subsequent separation. Nickel is then deposited directly upon this surface, after which alternate layers of copper and nickel are deposited until any desired thickness is obtained, which thickness is merely sufficient to insure reasonable rigidity when handling the alto in subsequent operations. This alto then serves as a form upon which to deposit the actual printing plate, known as the "basso," which is an exact duplicate of the original plate. Needless to say every precaution must be taken in these operations to avoid the presence of bubbles or foreign particles upon the surfaces during the initial deposition.

For the production of a durable printing surface the most promising metals are probably nickel, cobalt and iron. A few experiments were made upon cobalt deposition which, while by no means exhaustive, indicated that at least with our present knowledge satisfactory deposits can be more uniformly obtained from the nickel baths than from cobalt. A few experiments have been carried out by us upon the possible application of iron, but it was concluded that this method could not be considered for immediate adoption. As opportunity offers, further work will be done with cobalt, iron and other metals.

NICKEL DEPOSITED IN PRESENCE OF FLUORIDES

It is not difficult to obtain nickel deposits of great hardness, but unfortunately this hardness is usually associated with brittleness and with consequent curling and cracking of the deposit. It was found that by the addition of hydrofluoric acid or fluorides to the nickel solutions, as recommended some time ago by E. G. Lovering of Detroit, it is possible to employ higher current densities and to obtain deposits of greater tensile strength than in corresponding solutions containing chlorides instead of fluorides.¹ Satisfactory results have been obtained by using either nickel fluoride (prepared by the solution of nickel carbonate in hydrofluoric acid) or sodium fluoride. Operating at a current density of about 20 amp. per sq.ft. it is possible to obtain deposits of nickel up to a thickness of 0.02 in. or more with a tensile strength considerably over 100,000 lb. per sq.in. Some deposits have proved very satisfactory upon the printing surface. Up to this time no reliable means of measuring the "abrasion hardness" of thin layers of

metal has been developed, but as a first approximation it has been assumed to be proportional to the ultimate tensile strength.

As above noted, the use of alternate layers of copper and nickel leads to the production of plates of very much greater tensile strength than can be obtained with copper alone. Microscopic examinations of deposits thus produced shows that the beneficial effect of the nickel is not due alone or principally to the greater tensile strength of the nickel, but rather to the effect upon the structure of the deposited copper produced by the interdeposition of layers of nickel. The presence of each layer of nickel prevents further growth of the copper crystals and thereby causes the layer of deposited copper to have a higher tensile strength than it would if it consisted of coarse crystals. The use of nickel layers is also a great advantage in reducing the tendency to form trees, a tendency which is particularly objectionable in the production of thick deposits of copper at relatively high current densities. Except for the presence of the nickel layers it would be impossible to use the current densities here employed for copper deposition without producing very rough and badly treed deposits, which would require an excessive amount of labor for finishing and would represent a considerable waste of material.

PREPARATION OF THE BASSOS, OR PRINTING PLATES

In the actual production of the bassos, or printing plates, an initial coat of nickel is deposited at 10 to 20 amp. per sq.ft. for 6 hours and which has therefore a thickness of about 0.005 in. Alternate deposition of nickel and copper for periods of one hour each is then continued for about six days. The current density used for nickel is about 20 amp. per sq. ft. and for copper about 50 amp. per sq.ft. so that the relative thicknesses are approximately in the ratio of 1 to 3—in other words, the plates contain about 25 per cent of nickel. A final layer of copper is deposited for one or two days. This latter material is largely removed in the subsequent machining operations. Its principal purpose is to fill up any small depressions that may exist at the end of the alternate deposition.

After separation the plates are machined and ground by means of appropriate equipment to a thickness of 0.25 in. and to the desired size. Plates prepared in this way are now being used successfully for the printing of securities and are yielding impressions fully equal in appearance and accuracy to those prepared from steel plates. The present average service of the plates is about 40,000 impressions. It is believed, however, that by further improvements and by increased experience in the methods of using such plates this service may be appreciably increased.

Numerous details of the process are still under investigation. When these studies are completed it is expected to publish as a technologic paper of the Bureau of Standards a detailed description of the plant and equipment used for this purpose. The experimental work upon this process was conducted largely by W. E. Bailey, L. D. Hammond and H. E. Haring of the Bureau of Standards. Valuable suggestions and advice were received from George B. Hogaboom, electroplating adviser of this Bureau, and Charles Barbour, assistant superintendent of the electrolytic plant at the Bureau of Engraving and Printing.

Note on Notched Bar Impact Tests and Toughness of Monel Metal

BY R. G. WALTENBERG*

THE notched bar impact test occupies probably the unique position of being at the same time the oldest mechanical test known and one of the youngest in point of development with modern mechanical apparatus and measuring devices. The first one to apply this test was unquestionably the smith who used it first to break his bars and later to test roughly their quality. It was not until 1884 (Tetmajer), however, that the test was brought into a quantitative form by the measurement of the energy required to fracture a notched bar by a single blow. Since that time many prominent investigators have been associated with its development—Barba, Fremont, Vanderhey, Charpy, Guillery, Martens, Heyn—and one can scarcely fail to be impressed today at its growing usefulness and importance in the testing and investigation of materials. Particularly in the field of alloy steels has the growth of its application been most rapid during the past few years, until it has been included in many commercial and government specifications for these materials.

THE CHARPY AND IZOD TESTS

The test is now so well known that only the briefest mention of two of its more common forms is warranted in this place. In the Charpy impact testing machine the test-bar is supported horizontally at both ends on a double anvil and struck at the center by a weight swinging as a pendulum in a plane perpendicular to its axis. From the known height from which the center of gravity of the pendulum bob was dropped and the vertical distance to which it rises as it swings through after bending or fracturing the specimen, the energy may be computed which was absorbed in the deformation or fracture of the specimen, and this energy, expressed in foot-pounds or kilogram-meters, is the result as usually expressed of the test.

In the Izod, or the Olsen, machine one end of the specimen is clamped vertically in a vise and the pendulum bob swings down over the vise and strikes the specimen at a specified distance above the vise; the same method is used of measuring and expressing the energy absorbed in fracturing the specimen. The notch in the specimen for the Charpy machine is in the middle of the beam and is on the opposite side from that which the hammer strikes, and in the Izod, the specimen is clamped with the notch even with the ends of the clamps and on the side on which the hammer strikes. In each case the notch is at the point in the beam where the value of the shear passes through zero and the fiber stress is maximum and in tension.

The relations between the size and shape of specimen, design of testing machine and of foot-pounds of energy absorbed in the test are at present so little known that it has been necessary to standardize carefully both the specimen and the machine in order that different experimenters may obtain concordant results. Thus the energy absorbed in fracturing a specimen is not proportional to its cross-section, as are tensile and compressive properties. In this country the usual specimen for these machines is 10 mm. square in section

with a 45-deg. V-notch, 2 mm. deep, with root fillet of 0.25 mm. radius, although some use a specimen of the same size but with slightly different type of notch.

VALUE OF THE NOTCHED BAR IMPACT TEST

It has been generally recognized that the notched bar impact test reveals properties and defects which are not usually shown in the results of the more common static tests such as the tensile, the torsion or the transverse bending test. In particular the result of this test expressed in terms of energy required to rupture seems to be the best single indication we have to date of the toughness, or conversely, the brittleness, of a material. It has therefore achieved perhaps its principal popularity with the users of alloy steels for automobile and aircraft construction, since the materials in these classes of service are subjected to rapidly applied stresses on parts with abrupt changes in cross-section.

In the non-ferrous field the impact test has been used chiefly up to the present time in the testing of light aluminum alloys,¹ but it appears that in this field also its usefulness and importance are growing rapidly. It has appeared worth while to carry out a brief series of impact tests on another prominent non-ferrous alloy, Monel metal, in order both to obtain additional data from which we might judge of the usefulness of the test in the non-ferrous field and to see what light the test would throw on the toughness property of this alloy.

TESTS ON HOT-ROLLED MONEL METAL RODS

At the suggestion, therefore, of Dr. Paul D. Merica of the International Nickel Co., tests were carried out, both with the Charpy and with the Izod machines at

of the machine and specimens are given by E. H. Dix. *Proceedings, A.S.T.M.*, vol. 19, p. 720, 1919.

The results of these tests are shown in Table I. The average of five impact tests with the Charpy machine on specimens cut from 1-in. hot-rolled Monel metal rods was 166 ft.-lb., and on specimens cut from $\frac{3}{4}$ -in. rods the average was 153 ft.-lb. The tests with the Izod machine were not satisfactory, as none of the specimens fractured and in some cases the hammer failed to pass the specimens. Attention may be called to the fact that in the Izod test the angle of bend is about 60 deg., while in the Charpy tests it is about 120 deg. The values of the impact energy absorbed in these tests are extraordinarily high and may usefully be compared with values which have been obtained on essentially similar specimens of other materials by other investigators and of which a compilation is given in Table II. It is most interesting that the energy absorbed in fracturing Monel metal in impact is much

* Product of tensile strength and elongation divided by $2 \times 100 \times 12$.

greater than that required to fracture any other materials of which the author has seen the record of tests, including even heat-treated alloy steels. This would indicate a very uncommon degree of toughness, surpassing that of the steels.

A little consideration will show, however, that this fact is not entirely unexpected. Until the advent of the impact test, engineers had been in the habit of combining those tensile values—tensile strength or yield point—which are indicative of strength with those—elongation or reduction of area—which are indicative of ductility in some manner to give a single expression as an indication of toughness. Thus a simple manner of doing this was to integrate the area under the stress-strain diagram of the tensile test of a material, which is the energy required to rupture the specimen in static tension. Still simpler is the method of multiplying the elongation in per cent by the ultimate

tensile strength, which is also of the dimensions of energy and not greatly different from the value obtained by integration of the stress-strain diagram. In Table III are shown average values of these quantities for some materials together with their product in each case expressed in foot-pounds per square inch of cross-section. This quality factor of toughness for Monel metal is again seen to be greater than that of any other material.

For the benefit of those who might wish to compare this property of Monel metal with any of its other physical and mechanical properties the following summary is given of the approximate average physical and mechanical properties of Monel metal in the hot-rolled condition as determined by various observers:

Tensile strength (1-in. hot-rolled rod), lb. per sq.in.....	94,600
Yield point (tension), (1-in. hot-rolled rod), lb. per sq.in.....	63,100
Proportional limit (tension), (1-in. hot-rolled rod), lb. per sq.in.....	40,000
Elongation in 2-in. (1-in. hot-rolled rod), per cent.....	40
Young's modulus, lb. per sq.in.....	23,000,000
Brinell hardness (3,000 kg.).....	160
Specific gravity of rolled Monel.....	8.97
Electrical resistivity, microhms per c.c.....	42
Electrical resistivity, ohms per mil-ft.....	256
Thermal conductivity, cal. per deg. C. per sec. per c.c.....	0.06
Thermal expansivity, per deg. C.....	14.0×10^{-6}
Melting range, deg. C.....	1310-1350
True specific heat, cal. per g. per deg. C.....	0.104
Optical reflectivity, per cent.....	60
Magnetic induction for $H = 100$, gauss.....	1,500

Coconut Oil Export From the Philippines

The total export of coconut oil from the Philippines during the first quarter of 1921 amounted to \$4,854,985, which was \$264,196 more than the export for the same period in 1918, but \$2,816,551 and \$3,562,952 less than the exports for the corresponding periods of 1920 and 1919, respectively. The highest single monthly exportation during the four years mentioned was in January, 1919, when the shipments of oil from the Philippines totaled \$6,098,069, at an invoice value of 30c. per kilo. The United States and the Netherlands were the only countries that absorbed the exports for the first quarter of 1921, while in previous years Great Britain, Spain and France shared a good portion of the Philippine output. Of the total export for this period \$3,190,407, or approximately 66 per cent, went to the United States; \$1,661,668, or about 34 per cent, to the Netherlands; and \$2,910, or less than 1 per cent, to all other countries.

The copra exported for the first quarter of 1921 was valued at \$1,912,133. That the copra trade is becoming active is shown by the fact that for the first quarter of 1920 the total export was \$10,148 only. In 1918 and 1919 the total exports of copra for the first quarters were \$122,219, and \$3,036,871, respectively, states the *Bulletin* of the Philippine Government Commercial Agency.

Legal Notes

BY WELLINGTON GUSTIN

George Patent for Cooling Bed Held an Advance in Art and Valid.

The United States District Court, in the case of the Morgan Construction Co. vs. the Donner Steel Co., held the George patent, No. 863,841, valid as making an advance in the art in which it is used. This patent relates to improvement in conveyors for metal rods used in rolling mills, and commonly called cooling beds.

The object of the inventor was to make the supporting and lifting bars of such shape and form that, when acting in combination, they would serve to hold the heated metal in contact and automatically straighten it while being moved step by step or by intermittent movements from one end of the cooling bed to the other. The specification stated that the inventor does not wish to confine himself to the curved form of the supporting surfaces of the lifting bars, as the desired result was achievable by other forms.

The steel company defended the suit on the grounds of lack of novelty and invention and non-infringement. The evidence showed that in making steel ingots, billets, bars, etc., of varying lengths, the heated metal as it emerges from the run-out of the mill is ordinarily cooled on a conveyor or cooling bed before it is handled. A large number of separate pieces of hot metal are usually placed on the cooling bed, arranged side by side and moved intermittently across it. It is desirable that the metal bars or billets should not in their heated condition come in contact with one another, as experience has shown that by contact they are often bent or distorted; and hence it is necessary that they should be moved on supporting surfaces, which help to prevent or correct any curves or bends in them. To accomplish this the supporting members of the device in suit are notched, and the notches aligned with corresponding wave-shaped depressions in the lifting member, so that the lowest part of the notches upon which the heated metal rests comes in the same plane with the depressions on the lifting member.

INVENTION NOT A GENERIC ONE

The court says the invention was not in any sense a generic one. The separate elements of the combination of the claims in suit were old, but the inventor was the first to combine in a single apparatus the step by step arrangement present in the known straight-edged bar device and in old devices with serrated edges on bars or skids aligned for carrying the hot rods by a rocking or oscillating mechanism of the skids or bars.

The prior patents issued to Johnston, to McDonald and McKee for so-called shuffle bar conveyors, to Edwards, to Kellogg for gravity notched cooling beds, to Geer, the so-called Illinois and Republic and Austrian cooling beds, disclose types of known devices. Such structure the patentee designed to improve, since the hot rods were bent in their travel in the shuffle bar conveyors, while the rocking and gravity devices operated on a different principle.

The court found in none of these the elements combined as in the patent in suit. By his new combination of old parts or elements separately shown in prior de-

vices the court thought the patentee advanced the art a little, producing a new and useful result, one operating upon a somewhat different idea from prior patents. The law is that a combination of old elements, if they have been combined to operate in a new way or to accomplish a new and useful result, is patentable.

The defendant company in its cooling bed adapted a similar combination to plaintiff's patent without having any prior actual knowledge of this patent. And since the serrations on the surface of the lifting support are of different shape, defendant claimed that a departure from the patent in suit resulted by its adoption, that a new use eventuated, in that the hot bars, after being lifted by the sides of the serrations, are allowed to slide or tumble to the bottom as they are carried over the edged surfaces of the stationary support. The court thought that the tumbling or sliding action of the hot rods after the lifting began was due in the main to lateral adjustment of the serrated bars and to the form of the serrations. And the changes in the serrations were changes of form only, and any improvements resulting therefrom were such as a skilled mechanic could make.

Finally, it was contended that plaintiff's device is impracticable since only one cooling bed had actually been constructed, its construction being under the broad claim only. But the court held that the utility of the invention is established by the fact that defendants have persisted in infringing it. (*Cf. Rumfort Chemical Works vs. New York Baking Powder Co.*, 134 Fed., 385.)

The court further says that under our laws a patentee is not obliged to manufacture the apparatus described in the patent. Its non-use does not deprive him of the protection of the patent laws.

Quality of Motor Gasoline

That the quality of gasoline has been maintained despite the fact that the stocks on hand at the refineries have been the greatest on record and that retail prices have been materially reduced is indicated by preliminary data obtained from the examination of samples collected in Washington, D. C., by the United States Bureau of Mines in its fourth semi-annual survey of the motor gasoline sold commercially throughout the country. While the average quality of gasoline now being sold is very similar to that sold a year ago, there is a noticeable difference in the shape of the distillation curve, due presumably to the increasing use of benzene blends in the eastern part of the country. The preliminary figures also confirm the deductions of previous surveys that there is a decided difference between the gasoline sold in summer and that sold in winter.

The average boiling point of gasoline sold in Washington a year ago was 279 deg. F. Today it is 278 deg., a negligible difference. Last winter the boiling point averaged 270 deg., and the winter before 267 deg.

Below are given the average distillation figures for the samples so far collected in Washington. While there is little change in the average boiling point as compared with a year ago, the difference in the actual character of the fuel, indicating increased use of benzene blends, is particularly noticeable at the 50 per cent point:

	First Drop	20%	50%	90%	End Point

July, 1921.....	128	202	259	390	445

Chicago's Relation to the Future American Steel Industry

An Analysis of the Economic Location of a Steel Industry in View of Modern Practice in Coal Economy, Diminishing Ore Tenor, Increasing Amount of Scrap Used, and the Greater Influence of Freight on Finished Product

By GERARD DE GEER
Nyhammar Steel Works, Sweden

"THE ore comes to the fuel," says a well-known rule in reference to the location of a steel plant. The past history of the steel industry over the whole world has proved the correctness of this expression. The center of gravity of the steel industry in the United States is consequently placed near the large coal and oil fields, and the ore is transported from other places. The German steel industry has been developed around the coal fields of Westphalia and Silesia, with the ore imported chiefly from France and Sweden. England is so fortunate as to have the coal and ore supply in common; at several places the ore and coal are even brought up from the same mine shaft.

In a natural way the location of the steel industry was determined by transportation facilities. If we go back half a century, when modern steel industry on a large scale began to develop, we find that it required about 2.3 tons of ore to produce 1 ton of manufactured steel with a consumption of 3 to 4 tons of coal. Under such circumstances it was considerably cheaper to transport the ore to the coal than *vice versa*.

DIMINISHING FUEL REQUIREMENTS

The question, however, is often raised whether these relations between ore and coal are fixed once for all and are unchangeable. It may be answered immediately. Certainly not. They are governed by the laws of progress. We find that the consumption of coal per ton of iron during the last decades has been gradually reduced, by a better utilization of the fuel combined with new metallurgical and thermotechnical methods. Formerly the gas from coke ovens and blast furnaces was allowed to waste into the atmosphere; nowadays this gas is very carefully collected and forms quite an important source for the production of heat and power. Formerly the steel was allowed to cool off between the different metallurgical processes. Now the pig iron is taken in a molten state from the blast furnaces to the steel-making departments, and the hot ingots are taken directly to the mills. The consumption of coal per ton of manufactured steel has accordingly during the last few years been reduced to about one-half the amount used fifty years ago, and it is safe to assume that the bottom level has not as yet been reached. Up-to-date modern steel mills need at the present time an insignificant amount of fuel in addition to the coke consumed in the blast furnaces. All other demands for heat and power are covered by the use of gas and tar from coke ovens and blast furnaces. Sometimes even an excess supply of gas or power is available which can be used outside the plant and which partly compensates for the quantities of coal that may be

necessary for certain purposes over and above the amount of coal for coking. Under such circumstances the coal supply is reduced to 2 tons or less per ton of manufactured steel.

DECREASING ORE TENOR

If we turn to the ore we will find the development to be in the opposite direction. A saving of ore in the same sense as that of coal is not possible. At all times practically all the iron has been recovered from ore smelted in the blast furnace. Small losses in slag and dusty gases are unavoidable, and even if they could be eliminated their importance would be insignificant. On the other hand, the consumption of ore per ton of pig iron is being gradually increased, due to a lower percentage of iron in the ore.

The best and richest ore is already mined and it becomes gradually necessary to use poorer ore. The average percentage of iron in the ore being used at the present time in the United States hardly reaches over 50 per cent, while a few years ago it was about 55 per cent. In Germany this retrogression is still more striking; there the average percentage of iron in ore has decreased from 54 to 41 per cent in forty years. A continued diminution of the percentage of iron in the ore is most likely to occur, even though it is partly counterbalanced by an increased number of ores which are concentrated.

One may readily ask the question whether or not the same condition prevails with regard to the deposits of coal—viz., that the best grade of coal has been consumed and that its quality decreases as mining continues. Such is not the case. When the upper coal strata have been mined it will be necessary to go deeper into the earth for further mining; the price of coal will be higher, but its quality, on the other hand, will be better rather than worse. The higher cost of mining leaves the question of transportation between mine and mill unchanged. Besides, the total supplies of coal are so enormously greater than the visible supply of what we now know as iron ore that shortage of the latter will ensue far sooner than of the former.

A table showing the relative distribution of the amount of transportation between manufactured products and the two most important raw materials, coal and iron, is given below, using the assumption that 1.25 tons of pig iron is required for 1 ton of ingots and 1.5 tons of coal for 1 ton of coke:

	1870	1920
Ore.....	2.3 tons, or 34.0%	2.5 tons, or 45.4%
Coal.....	3.5 tons, or 51.3%	2.0 tons, or 36.3%
Manufactured product...	1.0 tons, or 14.7%	1.0 tons, or 18.3%

From this table it is seen that the reasons for the location of the iron industry, judging from the transportation point of view, have been changed quite considerably. Ore and coal have almost changed places and the importance of transportation of manufactured steel in relation to the raw materials has increased. It is to be noted particularly that these changes have been accentuated in a considerable degree during the last two decades. Its consequences already show themselves in certain tendencies in the development of the steel industry. The rule mentioned at the beginning of this article, that the ore comes to the fuel, is nowadays a truth only with modification.

If one considers the steel industry of the United States he finds that an unquestioned movement has taken place in direction *from* the coal *to* the ore. Branches have reached out from the Pittsburgh steel center toward the north and met the Lake Superior ore, and toward the east to the imported ores. At present there is a steel district of considerable size at the south shore of Lake Michigan with Chicago as the center. A rapidly growing steel industry has also been developed near the earliest location of the American industry, the Atlantic coast around Boston, Baltimore and Philadelphia. It is shown by production statistics that these steel districts have grown considerably more rapidly than the original ones. For instance, the production of pig iron, in accordance with the official statistics of the United States, has progressed in the following manner during 1900 to 1918 in the two districts as given below:

Year	Pennsylvania, Tons	Illinois and Indiana, Tons
1900.....	6,365,935	1,527,095
1910.....	11,272,328	3,925,749
1918.....	15,198,271	6,513,906

Pennsylvania is the home of the original steel industry of the United States and maintains still a predominant position in comparison with other states. The two other states as given in the above table represent a new steel district, which has grown up in the last thirty years at the south end of Lake Michigan. The percentage of increase within the latter district from 1900 to 1918 has been 326 per cent, while the corresponding figure for Pennsylvania is 140 per cent.

In judging the question of ore versus coal it will be necessary to give some attention to the fact that not all kinds of coal are suitable for the steel industry. For example, in order to obtain good coke for the blast furnaces a special brand of coal is required. It is true that there are enormous supplies of coal in Indiana and Illinois, and on that ground it seems absurd to talk about a movement toward the Mesabi ores *from* the coal which is to be used for the steel industry that has been located in that district. These coal supplies are, however, of such a quality that they are not, as a rule, suitable for production of coke without mixing. The largest part of coal used for coking by the Chicago industries is consequently taken from the coal fields in Pennsylvania and Kentucky.

ILLUSTRATIONS FROM EUROPE

Movement of the steel industry toward the ore can be shown more distinctly in Germany. About thirty years ago there was hardly any steel manufactured in Lorraine (now French). At the present time the coal comes from Westphalia and the Saar district and to a

large extent is transported to the western part of the country, where a rapidly growing steel industry has been developed around the large ore fields of Lorraine. The more important steel and iron districts of Germany proper also show the same tendencies of evolution. Thus, the steel interests in Upper Silesia have sent branches to the Baltic Sea, where a couple of large steel mills have grown up, using Swedish ore and Silesian and Westphalian coal.

INFLUENCE OF SCRAP

In judging the influence of transportation on the steel industry due consideration must also be given another factor of rapidly growing importance. An investigation of the statistics of production in the United States shows that a replacement has occurred in the relations between the tonnage of pig iron and of steel. Up to 1910 the former was greater than the latter, but since 1911 steel has outdistanced pig iron, as is shown in the following table:

Year	Pig Iron, Tons	Steel, Tons
1890.....	9,202,703	4,277,071
1895.....	9,446,308	6,117,834
1900.....	13,789,242	10,188,329
1905.....	22,992,380	20,023,947
1910.....	27,303,567	26,094,919
1911.....	23,649,547	23,676,106
1915.....	29,916,213	32,151,036
1917.....	38,647,397	45,060,007

The thing which has caused this reversal is the use of scrap iron in the manufacture of steel. Scrap iron has therefore become a third standard raw material for the steel industry, competing in importance with the older two, ore and coal.

Daily experience tells us that only an insignificant part of the enormous quantities of iron which are being discharged into the world's markets is destroyed in the true sense of the word. Much the largest part of it is saved from the destroying elements and sooner or later it is returned to the steel mills in the form of scrap iron. Through this cycle the loss of ore and coal as well as of labor will become less in spite of the growing demand for iron.

The period required for this circulation of iron is naturally quite variable. Steel from which tools and machines are fabricated can be used only for a few years; in rails and ship plates it lasts 10 to 40 years, but when steel is used as building material and reinforcement for concrete construction its life may be hundreds of years. The transposition of a steel product into scrap iron is in a large measure dependent upon other factors than the real wear and tear or the disintegration of the iron. The many technical advancements and the ever-continued progress in every line of business have become a factor of enormous importance in producing scrap iron. All kinds of machinery are being scrapped because they are not modern and up to date; rails are being exchanged, not because they are worn out but for the reason that increased train speed requires heavier locomotives and stronger rails; perfectly good buildings are torn down and replaced with new ones because they no longer correspond to the increasing demand for hygiene and comfort. The real disintegration of iron is less than is generally conceded. It is reduced chiefly to such objects as shoe tacks, horseshoe nails, rims on wagon wheels, etc., or is caused by accidents, such as shipwrecks and fires. In a machine that weighs about 10 tons only a few pounds

of its metallic contents are subjected to real wear—as for example the edge of a tool. Worn-out rails have in many cases lost only a few per cent of their original weight; in fact the formation of rust is usually a more dangerous enemy to iron than mechanical wear.

IRON CIRCULATING IN FABRICATION PROCESSES

The time has not yet arrived when the effects of the circulation of iron have become felt to the full extent. We must realize that the production of iron on a large scale commenced only with the introduction of the bessemer and open-hearth processes during the latter half of the last century. Before that the world's production could without difficulty be produced at the present time in a couple of the larger steel mills in the United States. We are now living in a period when the return flow of used-up iron to the steel mills has just started. There can be no doubt that this flow will grow in size.

As late as at the beginning of this century practically all the steel was produced from pig iron—that is, directly from ore. The older metallurgical methods did not permit of anything but a very limited use of scrap iron. Conditions are entirely different now. It is hardly possible to say exactly how large a part of the steel comes from pig iron and how large a part from the addition of scrap, as this figure cannot be obtained directly from the statistics. Consideration must be given to the fact that not all of the scrap iron used is material which has been returned to the steel mills as an actual increase of the raw materials, but that part of it is a waste product in the mills themselves, formed during the process of fabrication, defectives, crop ends and trimmings. Because the statistics usually show the production of steel in form of raw ingots the iron that comes from this continuous circulation within the mill will be included in the figures for the total production.

SCRAP WITHIN THE MILL

Were it possible to count the production in manufactured goods, then the condition would be different, but this cannot be done for the reason that the line between partly manufactured goods and completely finished products is very changeable. It is true that the largest part of the products of the steel mills is shipped direct without further treatment—such as, for example, rails, structural shapes and pipes. A considerable portion, however, undergoes additional processes of fabrication, resulting in a certain amount of scrap—for example, all iron which is delivered to machine shops. Scrap iron from these industries must be counted in the same class with that of the steel mills. It is not an actual addition to the supply, but must rather be considered as part of the unavoidable circulation; the time cycle involved is hardly longer than for the scrap iron produced within the mill itself.

A calculation which cannot necessarily claim to be exact but which in all probability comes pretty near reality will show that the iron that comes from this circulation during its production and further fabricating processes corresponds to 20 per cent of the weight of the produced ingots. In order to conceive the importance of the real circulation of iron—that is, the quantity of iron which has actually been in use, worn out or scrapped for any other reason and then returned to the steel mills—it will be necessary first to reduce the statistical figures for production of ingots

by 20 per cent and then to calculate how much of the remaining portion comes from the pig iron and the scrap iron respectively.

STEEL FROM BONA FIDE SCRAP

If the American production of ingots during 1917 is used as a basis for the calculation, it will be shown that about 82.5 per cent of the weight of iron comes directly from the ore and the remaining 17.5 per cent from the real scrap. The calculation has been made as follows: The production of ingots during 1917 in the United States was 45 million tons. From this is deducted 20 per cent, that portion derived from iron circulating in the manufacturing processes, leaving 36 million tons. The production of pig iron during the same year was 38.6 million tons. In order to determine how much of this pig iron was finally obtained as steel it will be necessary to reduce the above figure not only by the production of iron castings (about 14 per cent) but also by the iron losses which follow the change of pig iron to steel (about 9 per cent). Final figures are thus: The

portion of pig iron $38.6 - \frac{23}{100} \times 38.6 = 29.7$ million tons. The amount of scrap iron entering into the ingots must then be $36 - 29.7 = 6.3$ million tons, or 17.5 per cent.

Considering the effect of scrap iron on the relation between transportation and the production of iron in accordance with the above the following tabulation may be made for the year 1917:

Ore.....	2.05 tons, or 41.0 per cent
Coal.....	1.75 tons, or 35.0 per cent
Scrap.....	0.2 tons, or 4.0 per cent
Manufactured product.....	1.0 tons, or 20.0 per cent

It must be stated that these figures do not pretend to be fully exact, because they are partly based on deductions and assumptions. The object of this article is, however, to give a picture of the general trend of progress and not to show complete statistical calculations. It is further assumed that the errors which eventually may be found in the above figures are not great enough to affect perceptibly the final conclusions.

From this tabulation it is shown that the third great class of raw materials has not as yet affected the question of transportation as related to the steel industry to any extent. The conclusions drawn when consideration was confined to the ore and coal are in a broad sense unchanged. The relative importance of transportation to the disposal of the manufactured goods has, however, increased somewhat.

I repeat that the movement of the steel industry from the coal toward the ore, the beginning of which is already distinctly noticeable, will with all probability be more and more accentuated in the future. Of course we can never expect any complete move in this direction, as a certain equilibrium will be established under the influence of the possibilities for return freight among other factors. Market for manufactured steel and the increasing importance of the scrap supply will in the future exert a greater influence upon the choice of new locations for a steel plant. The question of railroad accommodations will be decisive in relation to both factors. It is necessary to have good transportation facilities to already established markets, as well as, and particularly, to the new fields which the future will probably open for the consumption of iron. An effec-

tive utilization of the scrap iron is altogether dependent upon the transportation facilities. The supply of scrap is not concentrated; it is made up from a multitude of smaller supplies located at places far apart. A net of transportation lines is required in order to collect the scrap and transport it to the place where it is to be used. The railroads themselves are, for that matter, big iron users as well as scrap producers.

ECONOMIC ADVANTAGE OF CHICAGO DISTRICT

It must be admitted that hardly any steel-manufacturing district in the United States has such favorable future possibilities as the Chicago district when judged according to above-given viewpoints. Its location corresponds to the economical equilibrium between the coal and the ore. It is situated in the focus of the greatest outbranching network of railroads in the world, with the gate open toward west and north, where new and great market possibilities are waiting. Its shores are washed by an inland sea offering favorable means for supply and distribution, a lake which may become a bay of the Atlantic when the plans for new connecting canals are realized. The leading position of Chicago in trade and communication will reach out to include also the most important of all industrial products—steel.

Exports of Chemicals During the Past Fiscal Year

ACCORDING to the Bureau of Foreign and Domestic Commerce reports, the fall in value of our exports of chemical products during the present industrial depression has not been much during the last four months of the fiscal year, ended June 30. As compared with the figures for the corresponding months of 1920, this group of exports showed a decrease of 54 per cent in February, 72 per cent in March, 70.6 per cent in April, 75.3 per cent in May, 73.3 per cent in June. The total value of the shipments during the latter month was \$4,178,685, as compared with \$15,685,322 in June, 1920, and \$4,366,119 in May, 1921. Three items only show an increase in 1921 over the export total for June, 1920; glycerine advanced in amount from 44 short tons to 52 short tons; its value, however, fell from \$21,638 to \$18,740. Calcium acetate increased from 13 tons (\$6,714) to 898 tons (\$29,212). Benzene, as during the preceding months, registered a notable upward movement from 590 tons (\$79,728) to 2,920 tons (\$187,237).

ARTICLES SHOWING LARGEST FALLING OFF

The articles which suffered most seriously in this fall were the following:

Nitric acid, 44 tons to 4 tons; miscellaneous coal-tar crudes, \$890,530 to \$35,163; copper sulphate, 193 to 28 tons; coal-tar dyes, \$2,389,515 to \$444,273; formaldehyde, \$212,925 to \$33,360; bleaching powder, 2,199 tons to 449 tons; petrolatum, \$322,431 to \$63,153; potassium chlorate, 255 to 16 tons; miscellaneous potassium compounds, \$304,616 to \$34,067; borax, 865 to 83 tons; caustic soda, 11,514 to 1,620 tons; soda ash, 7,341 to 2,130 tons.

COMPARISON WITH TWO PRECEDING YEARS

Far less serious was the shrinkage in the amount and value of our chemical exports for the fiscal year, ended with June 30, as compared with the two preceding years.

In 1919 the total value of such exports was \$148,053,531; in 1920 it was \$158,691,918; in 1921 it fell to \$110,284,401. This is a decrease of 30.5 per cent as compared with 1920, and 25.5 per cent as compared with the total for 1919. Increase over the 1920 figures is registered for four products. Bleaching powder advanced from 15,616 short tons (\$840,092) to 18,713 short tons (\$1,146,378); sodium bicarbonate, 5,999 to 6,672 tons; benzene, 8,627 to 33,311 tons; miscellaneous coal-tar crudes, \$3,618,424 to \$4,101,129. Soda ash fell from 58,727 to 56,741 tons, but the value rose from \$2,804,130 to \$3,308,783. The most noteworthy decreases in our exports of chemicals during the past fiscal year were as follows:

Baking powder and glycerine, 38 per cent; formaldehyde, 40 per cent; miscellaneous chemicals, 42 per cent; sulphuric and miscellaneous acids, 43 per cent; miscellaneous dyes, 47 per cent; roots, herbs and barks, 54 per cent; caustic soda, 56 per cent; borax, 57 per cent; all potassium compounds and calcium acetate, 61 per cent; nitric acid, 67 per cent; carbolic acid, 71 per cent.

HOLDING OUR SHARE OF FOREIGN MARKET

In view of the lowered prices of numerous chemicals it is evident that we are holding a fair share of the foreign market for these products, gained by our unceasing efforts during the war period. It is equally evident that only by a similar strenuous effort can the market over there be held in the face of the determined resolution of the German chemical trade to win back as much as possible of its control in this branch of commerce. The accompanying table furnishes comparative details of the movement into the world's consuming markets of our American chemicals and allied products during the fiscal years ending with January, 1920 and 1921:

EXPORTS OF CHEMICALS AND ALLIED PRODUCTS FOR THE FISCAL YEAR ENDING JUNE 30, 1920 AND 1921

(Quantities in Pounds Unless Otherwise Stated)

Acids:	1920	1921
Carbolic.....	\$2,223,305	\$659,890

Measuring Gases Containing Water Vapor

Accurate Measurement of Gases Saturated With Water Vapor Requires a Determination of Density—
Velocity Formulas Modified to Use Specific Gravity Values Determined
Graphically—Procedure for Partially Saturated Gases

By THOMAS G. ESTEP*

IN THE various industries where devices are used for measuring large volumes of gases it is found that practically all such gases contain a certain amount of water-vapor. Byproduct coke-oven, producer and blast-furnace gases are nearly always saturated with water vapor at the moderate temperatures, while atmospheric air is usually only partially saturated.

The necessity for correcting gas measurement for water vapor is often overlooked by engineers with the result that large errors obtain. The extent of such errors may be more appreciated by pointing out that in a particular problem which is referred to later in this paper, if the gas had been considered as dry instead of saturated, the error in the volume under standard conditions would have been 5.3 per cent. When it is considered that with the devices for measuring gases, if carefully handled, will give results correct within one per cent, it is apparent that the error due to neglecting the water vapor is much larger than the errors due to observation.

FORMULAS FOR VELOCITY

Of the various methods employed for measuring gases—Pitot tubes, Venturi meters, orifices and throttle disks—all produce a measurable differential pressure which bears some relation to the velocity of the gas. In the case of the Pitot tube, this differential pressure or head is directly proportional to the square of the velocity but in the case of the other devices mentioned, this head only represents change in velocity. Expressed in the form of equations: For Pitot tubes,

$$V_1^2 = 2gh$$

For Venturi meters, orifices and throttle disks where the differential pressure is small enough so that changes in specific volume of the gas may be neglected,

$$V_2^2 - V_1^2 = 2gh$$

Where

V_1 = velocity of gas in main pipe, feet per second.

V_2 = velocity of gas at smallest section, feet per second.

g = acceleration due to gravity, feet per second per second.

h = differential pressure expressed in feet of the gas at the pressure and temperature at the point of measurement.

The differential pressure h is usually measured in inches of water, oil or mercury. To convert it into equivalent feet of gas it is only necessary to divide by 12 and multiply by the ratio of the density of the water, oil or mercury to the density of the gas under the conditions at the point of measurement. This sounds comparatively simple but the labor lies in the determination of the density of the gas at the point of measurement

because it is the density of a mixture of gas and water vapor. This can be determined by chemical analysis, but the process, while not difficult, is very laborious. The density can, however, be calculated from more easily determined data.

CALCULATION OF DENSITY OF A MIXED GAS

To illustrate this method of finding the density of a gas when saturated with water vapor and the determination of the velocity of the mixture in the pipe, a concrete problem will be solved. Assume that the average velocity head of a certain gas has been determined by the Pitot tube and is 3 in. of water. The gas at the point of measurement has a temperature of 85 deg. F. and an absolute pressure of 34 in. Hg and is saturated with water vapor. The chemist reports that this gas, when dry at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg, has a specific gravity of 0.4 referred to air at the same temperature and pressure as unity. It is first necessary to determine the density of air at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg. This can be done by using the characteristic equation of a perfect gas.

$$d = \frac{P}{RT}$$

Where

d = density, pounds per cubic foot.

P = absolute pressure in pounds per square foot.

R = gas constant, foot pounds per degree F.

T = absolute temperature of the gas, degrees F.

Substituting,

$$d = \frac{144 \times .49117 \times 30}{53.34 \times (62 + 459.6)} = .07627 \text{ lb. per cu.ft.}$$

The density of the dry gas at 62 deg. F. and 30 in. Hg = $.07627 \times 0.4 = .03051$. By consulting the steam tables, it is found that at a temperature of 85 deg. F., the vapor pressure is 1.209 in. Hg. and the vapor density is 0.001832 lb. per cu.ft. If the total pressure of the mixture of gas and water vapor is 34 in. Hg and the partial pressure of the vapor is 1.209 in. Hg, then according to Dalton's law, the partial pressure of the gas in the mixture is $34.000 - 1.209 = 32.791$ in. Hg. In one cubic foot of the mixture there is one cubic foot of gas at a temperature of 85 deg. F. and an absolute pressure of 32.791 in. Hg and one cubic foot of saturated water vapor at an absolute pressure of 1.209 in. Hg. The weight of the one cubic foot of gas at a temperature of 85 deg. F. and an absolute pressure of 32.791 in. Hg is,

$$\text{weight, lb. per cu.ft.} = .03051 \times \frac{62 + 459.6}{85 + 459.6} \times \frac{32.791}{30.000} = .031940$$

*Associate Professor of Mechanical Engineering, Carnegie Institute of Technology.

The weight of the mixture of gas and water vapor per cubic foot is

weight of mixture, lb. per cu.ft. =

$$.031940 + .001832 = .033772.$$

This is the density of the mixture at the point of measurement.

The specific gravity of the mixture at the point of measurement, referred to air at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg as unity is,

$$\text{Specific gravity of mixture} = \frac{.033772}{.076270} = .4428.$$

The equivalent feet of gas corresponding to the 3-in. water velocity head is,

$$\text{Feet of gas} = \frac{3 \times 62.4}{12 \times .033772} = 461.92.$$

The velocity of the gas in the pipe is then,

$$\text{Velocity, ft. per sec.} = \sqrt{2 \times 32.16 \times 461.92} = 172.37.$$

It can be readily seen from the above that the determination of the density of the mixture at the point of measurement is rather laborious, hence a set of curves has been prepared from which the specific gravity of the gas when saturated with water vapor at various temperatures and pressures can be read directly, thus avoiding the tedious calculation. Two families of curves are given in the accompanying figure, one for a base of 62 deg. F. and 30 in. Hg and the other for 59 deg. F. (15 deg. C.) and 30 in. Hg. The abscissa of the curves at the right of the diagram is the temperature of the mixture at the point of measurement. The curves above are the specific gravities of the dry gas referred to air at the base temperature and pressure as unity. The straight lines to the left are lines of constant pressure of the mixture at the point of measurement while the abscissa for this set is the specific gravity of the gas when saturated with water vapor at the given temperature and pressure, referred to air at a temperature and

CURVES SHOWING VARIATION IN SPECIFIC GRAVITY OF GASES WHEN SATURATED WITH WATER VAPOR AT DIFFERENT TEMPERATURES

pressure corresponding to the base as unity. The dotted line shows how to use the curves for any condition.

Since these curves give the specific gravity of the mixture at the point of measurement the equations for velocity will be modified so that the values from the curves can be substituted directly. When air at 62 deg. F. and 30 in. Hg is taken as a base, for Pitot tubes the velocity is

Velocity, ft. per sec. =

$$\sqrt{\frac{2 \times 32.16 \times 62.4 \times H}{12 \times .07627 \times S}} = 66.22 \sqrt{\frac{H}{S}}$$

Where

H = velocity head, inches of water.

S = specific gravity of the mixture at the point of measurement referred to air at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg as unity.

When air at 59 deg. F. and 30 in. Hg is taken as the base; for Pitot tubes the velocity is,

$$\text{Velocity, ft. per sec.} = 66.02 \sqrt{\frac{H}{S}}$$

Where

H = velocity head, inches of water.

S = specific gravity of the mixture at the point of measurement referred to air at a temperature of 59 deg. F. and an absolute pressure of 30 in. Hg as unity.

For Venturi meters, orifices and throttle disks where the differential pressure is small enough so that changes in specific volume of the gas can be neglected, the equation for velocity becomes,

Velocity at smallest section, ft. per sec. =

$$K \times C \sqrt{\frac{H}{S \left[1 - \left(\frac{A_2}{A_1} \right)^2 \right]}}$$

Where

K = a constant = 66.22 or 66.02 depending upon what condition of air is taken as a base.

A_1 = inside area of main pipe where upstream pressure is measured.

A_2 = area of smallest cross section.

(Both these areas must be in the same units.)

C = orifice coefficient.

This coefficient for Venturi meters is usually taken as unity. For well-rounded or so-called standard orifices it varies from .95 to .99 depending largely upon the size of the orifice. For throttle disks, the coefficient varies greatly for different conditions and should be determined experimentally.

Where the differential pressure is great enough to cause an appreciable change in the specific volume of the gas as it passes through the device, then the above equation will not hold and the general equation for frictionless adiabatic flow must be used.

VOLUME DETERMINED FROM VELOCITY

After the velocity of the gas has been determined, if this velocity in feet per second is multiplied by the area of the section in square feet, the result is the volume of the mixture of gas and water vapor flowing, in cubic feet per second at the pressure and temperature at the point of measurement.

Very often the volume of dry gas at some standard condition, such as a temperature of 62 deg. F. and an

absolute pressure of 30 in. Hg, is wanted instead of the volume of wet gas. To find this, multiply the volume of the mixture by the ratio of the absolute gas pressure in the mixture to the absolute pressure at the standard condition and further, by the ratio of the absolute temperature at the standard condition to the absolute temperature of the mixture at the point of measurement.

For example; suppose that the area of the section in the problem already solved is such that when the velocity of 172.37 is multiplied by this area the result is, for convenience, 100 cu.ft. per sec. This means that there are flowing 100 cu.ft. per sec. of a mixture of gas and water vapor at a temperature of 85 deg. F. and a total absolute pressure of 34 in. Hg. The equivalent volume of dry gas at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg is,

$$\text{Vol. dry gas} = 100 \times \frac{32.791}{30.000} \times \frac{62 + 459.6}{85 + 459.6} = 104.5 \text{ cu. ft.}$$

In some cases it is desired to know the equivalent volume of gas when saturated with water vapor at some other condition of pressure and temperature as a standard. To illustrate; suppose that it is desired to know the equivalent volume of gas when saturated with water vapor at a temperature of 62 deg. F. and an absolute pressure of 30 in. Hg. From the steam tables, the vapor pressure at a temperature of 62 deg. F. is .560 in. Hg. The absolute gas pressure under the new conditions will then be 30.00 — .56 = 29.44 in. Hg and the equivalent volume at 62 deg. F. and 30 in. Hg is,

Volume saturated gas at 62 deg. F. =

$$100 \times \frac{32.791}{29.44} \times \frac{62 + 459.6}{85 + 459.6} = 106.7$$

PARTIALLY SATURATED GASES

So far, only the case where the gas is completely saturated with water vapor has been considered. When it is desired to determine the volume of air delivered by fan, compressors or turbo blowers and the measurements are made with sufficient accuracy to justify making a correction for water vapor, the problem becomes more involved due to the fact that in practically all cases the air is only partially saturated. In such cases the procedure would be as follows: Determine the wet and dry bulb temperatures of the gas at the point of measurement. From a psychrometric chart find the dew point temperature for this condition. Then from the steam tables find the vapor pressure and density corresponding to the dew point temperature and proceed as in the previous problem. This method is correct only when the total pressure is 30 in. Hg, for practically all psychrometric charts are based on this pressure and for any great variation in the total pressure from the above the relative humidity or the dew point should be calculated from the original equations. In nearly all cases in actual practice the total pressure of the gas at the point of measurement is nearly atmospheric so that the error from the procedure mentioned will be small.

TNT for Road Building

TNT, in the opinion of Thomas H. MacDonald, chief of the Bureau of Public Roads, is an ideal explosive for use in road construction. Through his bureau 26,000,000 lb. has been distributed for that purpose without an accident. As TNT does not freeze and the fumes do not produce headaches it is popular with road contractors.

The Training of the Glass-Works Chemist

BY ALEXANDER SILVERMAN

IN AN article which appeared recently in the *Pottery and Glass Record* and was reprinted in an American journal¹ Dr. W. E. S. Turner of the Department of Glass Technology of Sheffield University called attention to the lack of a course in Glass Technology in the curricula of our institutions of learning. The writer outlines the following course of study to "start the ball rolling," and invites discussion. Numbers indicate the actual hours per week scheduled for classes, the first figure signifying lecture and recitation hours, the second, laboratory.

FIRST YEAR

- First term.—General inorganic chemistry (4-6)
General physics (3-3)
Advanced algebra (5)
German (3)
English (3)
- Second term.—General inorganic chemistry (4-6)
General physics (3-3)
Trigonometry (5)
German (3)
English (3)
- Third term.—General inorganic chemistry (4-6)
General physics (3-3)
Analytical geometry (5)
German (3)
English (3)
- Fourth term.—Such general work in a glass factory as requires no special technical training.

SECOND YEAR

- First term.—Advanced inorganic chemistry (2)
Qualitative analysis (1-9)
Advanced physics (light) (2-6)
German or French² (3)
Analytical geometry (5)
- Second term.—Advanced inorganic chemistry (2)
Qualitative analysis (1-9)
Advanced physics (Heat) (2-6)
German or French (3)
Calculus (5)
- Third term.—Advanced inorganic chemistry (2)
Quantitative analysis (1-9)
Advanced physics (Study and determination of physical properties of glass) (2-6)
German or French (3)
Calculus (5)
Graphics (3 practice)
- Fourth term.—General work in a glass factory.

THIRD YEAR

- First term.—Physical chemistry (3-3)
Quantitative analysis (1-9)
Mineralogy (2-6)
Gas and fuel analysis (2-6)
French (3)
- Second term.—Physical chemistry (3-3)
Quantitative analysis (Raw materials for glass) (1-9)
Geology (5)
Fuel values. Pyrometry. (3)
French (3)
- Third term.—Physical chemistry (3-3)
Quantitative analysis (Glass) (1-9)
Microscopy (1-6)
Organic chemistry (2-6)
French (3)
- Fourth term.—Analytical laboratory practice in a glass factory.

FOURTH YEAR

- First term.—Clays and refractories (2-6)
Glass technology (2-6)
Ceramic calculations (2)
Engineering laboratory (2-6)
General economics (3)
Library work (5)
- Second term.—Glass technology (3-9)
Ceramic calculations (2)
Electrical engineering (2-6)
Economics (Factory management) (3)
Library work (5)
- Third term.—Glass technology (3-12)
Electrical engineering (2-6)
Economics (Labor and costs) (3)
Library work (5)

The writer considers it necessary to discuss only a few of the courses in detail, as most of those listed are familiar to all engaged in teaching. In the short courses in mineralogy and geology special attention must naturally be given to raw materials used in the glass industry. The course in microscopy should cover both microchemical and petrographic methods.

Under glass technology one should include furnace and lehr design; fuels; raw materials; preparation of batches; melting and refining; furnace control; glass manipulation; annealing; physical and chemical properties of glasses; manufacture of plate, window, bottle, illuminating, chemical, optical, water glass, table ware and fused quartz; etching, silvering, enameling and decorative processes; glass substitutes. The laboratory work should include the preparation of various glasses and the study of their properties. The course in ceramic calculations supplements that in glass technology and affords the student practice in the handling of mathematical problems encountered from time to time.

Some may think that the glass chemist is so specialized a being that there will be but little demand for him in the industry. The writer feels that with the training prescribed he will, with practical experience in the industry, develop into a very important factor.

As stated in the introduction the paper was presented to arouse discussion. This is earnestly invited.

Department of Chemistry,
University of Pittsburgh.

Statement of Austrian Iron and Steel Concern for 1920

The net profits of the Alpine Montan Gesellschaft, which comprises nearly all of the Austrian iron and steel industry, for 1920 were 28,564,704 crowns as compared with 10,697,928 crowns during the preceding year, according to a report received from C. H. Foster, with the American Mission, Vienna. The volume of annual sales for 1920 was 1,930,000,000 crowns against 246,000,000 crowns for 1919. On April 20, 1921, the company decided to pay on May 10 a dividend of 25 per cent, or 50 crowns, per share. Last year the dividend was 10 per cent, or 20 crowns, per share; in 1916 it was 50 crowns; and in 1912 it was 52 crowns per share.

The year seems to have been very prosperous, but the higher figures were really caused more by higher prices and a depreciated currency than by a greater quantity of production and economy of operation. In general, production at the end of the year was about 22 per cent of capacity. In comparison with the company's best year—1916—iron ore was produced at the rate of 18 per cent; pig iron, 14.5 per cent; rolled iron, 27.5 per cent; and steel, 24.5 per cent.

¹Glass Industry, vol. 2, 1921, p. 10.

²Students who have had three years of German should begin French.

Carbon Black From Natural Gas in 1920

BY E. G. SIEVERS

THE total quantity of carbon black produced from natural gas in the United States in 1920 was 51,321,892 lb. and 43,500,000 lb. in 1918. In 1919 the plants were still operating at or near full capacity on account of the war, but since normal conditions have been restored the production has decreased.

The output in 1920 was made by thirty-nine plants, operated by nineteen producers, whereas in 1919 only thirty-six plants were operated by sixteen producers. The total value as computed from the prices received by the producers was \$4,032,286 for 1920 and \$3,816,000 for 1919. The prices ranged from 4c. to 27c. a lb. in 1920 and from 3c. to 27c. in 1919. The average daily production in 1918 was 120,830 lb.; in 1919, 144,600 lb.; and in 1920, 140,608 lb.

About 40,600,000 cu.ft. of natural gas was consumed in the manufacture of carbon black in 1920, as compared with 49,896,200,000 cu.ft. in 1919 and 45,000,000,000 cu.ft. in 1918. In 1920 the production of carbon black per thousand cubic feet of gas consumed ranged from 0.45 to 2 lb., but the average production during the year for all states was about 1.26 lb., as compared with 1.04 lb. during 1919. Table I gives the range in production of carbon black at plants in the United States in 1919 and 1920.

TABLE I. RANGE OF PRODUCTION OF CARBON BLACK IN 1919 AND 1920

Production	Plants	
	1919	1920
Less than 1 lb.	6	6
From 1 to 1.2 lb.	17	19
From 1.3 to 1.6 lb.	11	6
From 1.7 to 2.0 lb.	2	8
	36	39

The daily capacity of the plants in volume of gas treated ranged from 172,000 to 20,350,000 cu.ft. as against 72,000 to 18,360,000 cu.ft. in 1919; the quantity of carbon black produced was from 90 to 23,250 lb. as against 90 to 22,900 lb. in 1919.

Tables II and III give the production by states for 1919 and 1920. West Virginia remained the leading producing state in 1920, although its output decreased 11 per cent. The annual decrease in production in West Virginia and in Pennsylvania is due in part to the diminishing supply of gas, which has made it possible to sell for fuel at higher prices large volumes of gas that would otherwise be used in making carbon black.

Louisiana, which has made rapid growth in the carbon black industry during the last few years and was second in rank, increased its production by 32 per cent

TABLE II. CARBON BLACK PRODUCED FROM NATURAL GAS IN THE UNITED STATES IN 1919

State	Number of Plants	Carbon Black Produced		Gas Used		
		Quantity, Lb.	Value	Average Price, c.	Quantity M. Cu.Ft.	Average Yield per M. Cu.Ft. Lb.
West Virginia...	23	29,925,614	\$2,358,119	7.8	23,117,332	1.3
Louisiana.....	7	14,024,606	933,334	6.6	20,291,021	0.7
Wyoming.....	1	4,868,947	231,747	4.7	4,306,153	1.1
Montana.....	1					
Oklahoma.....	2	2,922,274	244,726	8.3	1,954,129	1.4
Kentucky.....	1					
Pennsylvania...	2	315,500	48,114	15.0	227,700	1.3
	36	52,056,941	\$3,816,040	7.3	49,896,235	1.04

in 1920. The great supply of gas in the Monroe field accounts for this marked increase in production. Louisiana will continue to be a large producer of carbon black unless prevented by legislation.

Oklahoma produced no carbon black in 1920. The combined output of Wyoming, Montana and Kentucky decreased 4 per cent, so that Louisiana was the only state showing a substantial increase. The producing states, named in order of production and the percentage of the output they produced, are West Virginia, 52 per cent of the total output; Louisiana, 36 per cent; Wyoming, Montana and Kentucky combined, 11 per cent; and Pennsylvania, 1 per cent.

TABLE III. CARBON BLACK PRODUCED FROM NATURAL GAS IN THE UNITED STATES IN 1920

State	Number of Plants	Carbon Black Produced			Gas Used	
		Quantity, Lb.	Value	Average Price	Quantity M. Cu.Ft.	Average Yield per M. Cu.Ft.
West Virginia...	19	26,659,469	\$2,221,674	8.2	18,628,780	1.35
Louisiana.....	15	18,565,498	1,455,764	7.8	18,099,800	1.0
Wyoming.....	1					
Montana.....	1	5,850,313	326,424	5.6	3,673,108	1.6
Kentucky.....	1					
Pennsylvania...	2	246,612	28,424	11.5	197,290	1.2
	39	51,321,892	\$4,032,285	7.8	40,598,978	1.26

The carbon black industry migrates according to the available supplies of natural gas. West Virginia has always been the center of manufacture, but Louisiana and Wyoming have made rapid growth. As natural gas is an ideal domestic fuel, the consumers demand that it be reserved for domestic uses, and the carbon black industry has, therefore, migrated to localities where there are abundant supplies of natural gas for which there is only a small market or no market at all. The Monroe gas field, in Louisiana, one of the largest in this country, has been a favorable location for carbon black plants, for it is remote from large cities and towns and supplies but little gas for domestic uses, and the gas is sold at a fairly low rate, so that the carbon black industry has there become well established. The producers are now installing plants that remove the gasoline from the gas before it is consumed in the manufacture of carbon black, which is another means of conservation.

In Wyoming the conditions are somewhat similar to those in Louisiana. The general market for the gas produced there is small, so that the carbon black industry has been developed until Wyoming has surpassed Oklahoma and assumed third rank among the producing states.

A cubic inch of carbon black contains approximately 1,905,000 sq.in. of surface, whereas a cubic inch of lampblack contains only 1,524,000 sq.in. Carbon black therefore consists of finer particles and is superior to lampblack for use in both the printing and rubber industries.

Carbon black is an amorphous form of soft carbon produced by the incomplete combustion of natural gas. It is sometimes confused with lampblack, which is made by burning oil or some other raw material and which differs from carbon black in molecular structure and tinctorial strength as well as in quality and in use. Its lightness and fineness, freedom from gritty particles, miscibility with oil, intensity of color and remarkable covering power when mixed with other materials are among its essential qualities.

Carbon black was first made commercially in this country about 1864, when it was first used in making

printing ink. The growth of the industry has been stimulated by the rapid increase in the publication of books and newspapers, which demand a constantly increasing supply of carbon black for the manufacture of printing inks adapted to fast press work. The modern rotary printing presses now used by daily newspapers and printing establishments require an ink that will dry rapidly and yet permit the presses to be operated at a high speed—an ink that will flow freely, possess great covering power and make an instantaneous and legible impression—and an ink having all these qualities

TABLE IV. SUMMARIZES THE APPROXIMATE DISTRIBUTION BY USES OF CARBON BLACK IN 1918, 1919 AND 1920

Use	1918 ^a		1919		1920	
	Per Cent	Quantity, Lb.	Per Cent	Quantity, Lb.	Per Cent	Quantity, Lb.
Rubber.....	45	20,000,000	40	20,822,400	40	19,947,000
Printer's ink...	23	10,000,000	35	18,219,600	35	17,454,000

can be made by using carbon black. One pound of carbon black mixed with 8 lb. of oil and other chemicals will produce enough ink to print 2,250 copies of a sixteen-page newspaper of ordinary size or 90 copies of a 300-page octavo book. Prior to 1864 lampblack was used in making printing ink, but as carbon black proved to be superior for this use it rapidly displaced lampblack. About 35 per cent of the total annual output of carbon black is now incorporated in printing ink.

CARBON BLACK IN THE RUBBER TIRE INDUSTRY

The introduction of carbon black in the manufacture of rubber tires has been of considerable consequence in the rubber tire industry. The addition of carbon black, which is a reinforcing agent, has given the rubber greater toughness and resiliency, better traction and a longer mileage. It has increased the tensile strength and the elasticity of the tire about 25 per cent and 10 per cent, respectively. During 1920 a number of rubber tire manufacturers who formerly manufactured white tires have changed to the manufacture of "black tread tires," and are using considerable quantities of carbon black—indicating the increasing use of this product in the rubber industry, which consumes about 40 per cent of the output. The advantages of carbon black in making rubber tires have been established, but whether it is irreplaceable is still a matter of opinion among chemists.

About 10 per cent of the carbon black produced is used in the manufacture of stove polish, about 1 per cent in phonograph records, and about 2 per cent is distributed among miscellaneous uses, including black leather, black and gray paper, bookbinder's board, buttons, carbon paper, carriage cloth, celluloid, electric composition insulators, cement colorings, crayons, glazed paper, Chinese and India inks, marking and stenciling inks, artificial stone and black tile, paint, shoe polish, tarpaulins, type ribbon, varnish, etc.

Between 15 and 20 per cent of the output is exported. Before the war about one-third of the output was exported, but owing to unstable conditions the export trade has not resumed its normal proportions. Owing to the increased use of carbon black in the manufacture of rubber tires in this country, however, less of the product will probably be available for export.

Macroscopic Examination of Iron and Steel

A COMMITTEE on metallography, appointed by the American Society for Testing Materials, has proposed the following tentative methods for testing iron and steel. Criticism of the methods is invited; it should preferably be addressed to G. F. Comstock, Titanium Alloy Manufacturing Co., Niagara Falls, N. Y.

In order to show up both chemical and crystalline heterogeneity, sections of iron and steel are more or less deeply etched in order to bring out their macrostructure. In this way the persistence of the dendritic structure of castings even after much heat-treatment and mechanical working, physical unsoundness such as blowholes, gas cavities, porosity, fine internal cracks and flakes, discontinuities of structure such as found in welding, flow of metal as in pressing and forging, are brought out.

Suitable sections are cut, smoothed and then ground on various grades of emery paper in order to obtain a smooth flat surface. In some cases it is necessary to continue polishing through No. 0 and No. 00 French emery papers. Other similar papers of domestic manufacture are also available and suitable for this purpose. The sample ought to have a surface free from grease and dirt; if necessary it is then freed from all grease by cleaning with gasoline and then alcohol when it is ready for immersion in the solution.¹

SOLUTIONS USED IN ETCHING

Macroscopic etching of iron and steel was used as early as 1783 by Bergman. Many different solutions have been used and many of them are given by Campbell,² and more recently by Rawdon.³

Of the following, 1 (a) and 2 are recommended.

1. To show segregation and the like:

(a) Hot concentrated hydrochloric acid used at about 100 deg. C. A deep etched specimen may be printed with printer's ink.

(b) Etching for four to five hours with 5 per cent picric acid in alcohol.

2. To show variations in crystalline structure as well as segregation:

One to 2 g. of ammonium persulphate in 10 c.c. of water. This is probably the best reagent for developing this phase of the structure in iron and steel.⁴

3. To show the distribution of phosphorus.⁵

Various reagents containing copper chloride are used. The copper coats those portions which are low in phosphorus and leaves the high-phosphorus areas bright. It has recently been shown that nickel and other alloys give similar effects, also that oxide of iron acts in the same way. The accompanying list shows the various solutions which have been recommended:

Heyn:⁶ Copper-ammonium chloride, 10 g., water, 100 c.c. A somewhat weaker solution is better, the specimen being etched two or three times in fresh solution if necessary. The liquid is gently agitated. The coating of spongy copper forming on the face of the specimen is easily removed with a swab of wet cotton. Portions high in carbon, sulphur and phosphorus will have darkened. If the copper

¹For large sections various methods have been devised depending on the material. Surface grinding when carefully done gives excellent results.

⁶Heyn and Bauer, *Metallographic*, 1909, vol. 1, p. 21.

film adheres, a 0.5 per cent solution of ammonium persulphate will facilitate its removal.

Stead:⁷ CuCl_2 , 10 g.; MgCl_2 , 40 g.; HCl , 10 c.c.; H_2O , 20 c.c.; alcohol to 1,000 c.c. Dissolve salts in smallest possible amount of hot water and make up to 1,000 c.c. with absolute alcohol. For small specimens the reagent is applied drop by drop until structure is developed. The specimen is then washed with boiling water and then alcohol. Another method is to wash off the deposited copper with ammonia and so increase the contrast.

Le Chatelier and Lemoine:⁸ CuCl_2 , 10 g.; MgCl_2 , 40 g.; HCl , 20 c.c.; H_2O , 180 c.c.; alcohol, 1,000 c.c. Applied like Stead's reagent. Contrast can be increased by electrolysis, using a single battery cell, keeping the current below 50 milliamperes.

Rosenhain and Haughton:⁹ Fe_2Cl_6 , 30 g.; HCl , 100 c.c.; CuCl_2 , 10 g.; SnCl_2 , 0.5 g.; H_2O , 1,000 c.c. The copper adheres firmly. Pearlite areas remain bright. Ferrite darkened by deposited copper, the purest parts darkening the fastest. Pitting can be avoided by diluting the reagent.

LeChatelier and Dupuy:¹⁰ Ethyl alcohol, 100 c.c.; H_2O , 10 c.c.; CuCl_2 , 1 g.; picric acid, 0.5 g.; HCl (concentrated), 1.3 to 2.5 c.c., varying with material.

Oberhoffer:¹¹ Ethyl alcohol, 500 c.c.; H_2O , 500 c.c.; SnCl_2 , 0.5 g.; CuCl_2 , 1.0 g.; Fe_2Cl_6 , 30 g.; HCl , 50 c.c.

Humfrey:¹² Emery paper finish may be used for specimen. Copper ammonium chloride, 120 g.; HCl (concentrated), 50 c.c., more or less, H_2O , 1,000 c.c. The addition of HCl causes the copper deposit to adhere. Etching is therefore started with the neutral solution and continued until all traces of the scratches have disappeared. Then in successive applications the acidity of this solution is gradually increased up to the maximum. Alloy steels etch better with solutions of weaker acidity. After wiping away the deposited copper and drying, the surface is lightly rubbed with fine emery paper and the relief portions brought out in strong contrast. The selection may be printed with ordinary printer's ink applied to the surface by means of a roller.

Dickenson:¹³ First etch with 10 per cent HNO_3 . Then re-etch with Fe_2Cl_6 , 40 g.; CuCl_2 , 3 g.; HCl , 40 c.c.; H_2O , 500 c.c.

METHODS FOR INDICATING DISTRIBUTION OF SULPHUR

The distribution of sulphur is usually shown by the sulphur print method.¹⁴ A solution of 2 to 3 c.c. of concentrated H_2SO_4 in 100 c.c. of water is used to moisten a sheet of matt-finish photographic paper. The specimen with its surface smoothed either with a fine file or grinding wheel is pressed firmly on the paper on which a brown mark indicates the sulphur-rich areas. About sixty seconds is usually sufficient. The paper is then washed and fixed in hyposulphite solution.

With larger sections the paper is placed on their polished surface with care so that no air pockets occur. If a very dilute solution is used and a longer "etch" several prints can be obtained. Fresh solution can be added with absorbent cotton should the paper tend to become dry.

Considerable differences of opinion have arisen as to the meaning of the results obtained by deep etching in transversely fissured rails, etc., because the presence of cracks in the material previous to etching had not been demonstrated. The following method, however, can be used to locate them. The sample after careful polishing is magnetized and then immersed in kerosene or a

similar liquid containing very fine iron dust in suspension. The particles of iron dust collect upon the face of the specimen and orient themselves to correspond to the shape of the cracks because of discontinuity in the metal which causes a change in the density of the magnetic flux. The samples are then washed in clean kerosene to remove as much as possible of the excess iron dust which clings to the surface.¹⁵

According to several authorities their existence has been proved by annealing the specimens prior to etching, because a pronounced decarburized area then occurs around these cracks.

The camera should be arranged so that the specimen is illuminated by vertical light. After certain kinds of etching, e.g., ammonium persulphate, the surface should be immersed in water, alcohol or light oil. Large specimens may be covered with oil or glycerin.

The surface obtained by deep etching may be printed with printer's ink applied with a roller. The printing can be done on a glossy paper in a letter press. For small samples of wrought iron deeply etched a reproduction can be made using an ordinary ink pad and applying the specimen as in block printing.

The Condensation of Water Solutions of Furfural With Aniline

BY JACK P. MONTGOMERY AND E. S. ERNST

In a recent paper by Mains and Phillips¹ a resin, "furfur-aniline," was described and the optimum conditions for its production and application as a varnish stain were given. They used equal weights of furfural and aniline heated for one hour at 200 deg. C. in an open flask, or for three hours at 170 deg. C. in a flask attached to a reflex condenser. A gum which was hard and brittle at 25 deg. C., insoluble in water, soluble in benzene and in furfural was obtained. The saturated benzene solution gave a light brown stain on white oak and the saturated furfural solution a dark brown stain.

We have found that water solutions of furfural as dilute as 2 per cent, mixed with aniline and heated to 125 deg. C. in an autoclave for fifteen minutes, give a gum very similar to that described by Mains and Phillips, the chief difference being that the gum made by us gives a darker shade than that described by them.

When an excess of aniline is used with the solutions of furfural, the residue is oily and not brittle at 25 deg. C., but when the mixture is steam-distilled the excess aniline is separated and the residue is hard and brittle at 25 deg. C.

The preparation of water solutions of furfural is very easy, but the fractionation of the furfural is somewhat difficult² and there is always a considerable percentage, frequently up to 8 and 10 per cent, of furfural in the rejected water, according to our experience. If the furfural production is being carried on with a view to subsequent condensation with aniline, it would seem useless first to prepare pure furfural. If furfural is being prepared for other purposes, the rejected water from the fractionating process has enough furfural present to make its recovery as furfur-aniline profitable.

Effect of Lightning Striking an Acid Tank

BY PHILIP DE WOLF

AT 3:45 p.m. June 1, 1920, during a terrific rain storm, at the Old Hickory Powder Plant, now being developed by the Nashville Industrial Corporation, a 20 x 12 ft. vertical acid tank, containing about 200 tons of 89 per cent H_2SO_4 , was struck by lightning.

The 20 x 12 ft. tanks are arranged in pairs, 60 ft. from the nearest building, high enough above the

FIG. 1. ACID TANK STRUCK BY LIGHTNING

ground to feed by gravity to the circulation and storage tanks of the adjoining O. V. lines. At their closest point the tanks are only 3½ ft. apart. They are connected by overhead lines into the general acid system of the plant.

After the lightning stroke the acid began to pour out, and the fire department was called. Its activity was confined to flushing back the acid and confining it to the relatively small area about the tanks, where it was partly removed by the sewerage system, and partly absorbed by the sandy soil.

The tank had bulged at the top, wrecking the platform, and smashing some of the timbers in the main deck. The platform under the valves on the pipe line a hundred feet away was also wrecked, but no harm was done to the columns or foundations of the tank, outside of a little blackening of the wood due to carbonizing with acid.

The lightning naturally struck the tank at the top, but it was bulged out, not in, showing internal pres-

FIG. 2. TOP OF TANK, SHOWING DISTORTION

sure of considerable magnitude. This must have come from an accumulation of hydrogen inside, due to the action of the acid upon the iron, and this, with the air inside, exploded to water. Or possibly the heat vaporized enough of the acid to produce this pressure. While no temperature measurements were taken, the condition of the top of the tank, which is now coated with

a smooth oxide, apparently impervious to weather, shows that there was sufficient heat to start an explosion.

The top of the tank was bulged out 9 in. and all cast-iron fittings broken, but not a rivet was started, nor apparently a seam opened. The illustration shows the curious distortion of the top, how much more the plates were expanded than the single riveted lap joints.

The acid ran out only through the broken fittings.

The lower half of the tank still retains its original coat of paint, all around, showing that the high temperatures did not get down that far; presumably the plates cooled very fast on account of the rain and the large body of acid inside.

But the course of the lightning was not the shortest way to the ground, over the tank and down the wet wooden columns, but along a horizontal 3-in. pipe line for a hundred feet, where instead of following the line any further it jumped 12 ft. to the ground, wrecking the platform there.

Why it did not touch the big tank only 3½ ft. away is a mystery, as is also the fact that several acid pipe lines, paralleling the one it chose for a path, and as near as 4 in. to it, were not touched.

A New Development in Oil Burners

The early types of vaporization oil burners have been designed on the principle of boiling the oil indirectly and mixing the hydrocarbon vapors with air in the combustion zone. Carbon has always formed

troublesome deposits which were conducive of bad burner adjustment and incomplete combustion. Recently Dr. J. B. Garner, J. B. Anderson, G. A. Shaner and the staff of the National Gas Fellowship at the Mellon Institute of Industrial Research, Pittsburgh, have perfected a burner of novel design which gives promise of making 30 to 40 deg. Bé. distillate a first-class fuel at a price equivalent to 35c. gas.

The Peoples National Gas Co., the local branch of the donor of the fellowship, plans to exploit the burner, being influenced by the need of the conservation of its natural gas resources.

The essential feature of the design may be seen from

the cross-section of the burner given herewith. The oil is boiled by direct partial combustion during flow in the channel rings, producing a very hot vapor which is mixed with air under 0.5-oz. pressure in the combustion zone and completely burned. A very efficient flame results, an actual heat absorption of 56 per cent being obtained in commercial operation during a rise from 60 to 300 deg. F. The burner is lighted at an asbestos wick placed in the drip pan in the cone base.

The past year has been spent in demonstrating the practicability of this apparatus. When all serious imperfections in the apparatus had been removed by the inventors, it was submitted to the Underwriters' Laboratories, Inc., of Chicago, for inspection and test. These investigations were begun in July, 1920, and continued until January, 1921, when the approval and indorsement of the Fire Council of the National Board of Fire Underwriters was given.

The Jennings Steam-Turbine-Driven Return-Line Heating Pump

THE satisfactory performance of the Jennings Hytor vacuum heating pumps, operated by electric motors, has led the Nash Engineering Co. of South Norwalk, Conn., to develop a novel type of steam-turbine-driven return-line heating pump. The cross-section (Fig. 1) shows the general design of this unit, which consists of an air pump that exhausts the air from the system, a centrifugal pump to remove the hot condensate and return it to a feed-water heater or hot well, and a steam turbine to drive the unit; all mounted on one shaft and assembled in the same casing.

The Jennings turbine-driven unit is especially designed for use in connection with heating or drying systems where the pump is called upon both to maintain a vacuum on the heating system and to return the hot water and condensation against a pressure.

The unit consists of two independent turbine pumps built in one casing—one pump handling the air, the other the condensation, the air and condensation being separated in a receiver under vacuum before entering the unit. This arrangement makes possible the large saving in horsepower, because the condensation, which is only one-eighth of the volume handled, is alone delivered against discharge pressure, the air being delivered free to the atmosphere. Also the air is handled in a

FIG. 1. CROSS-SECTION OF JENNINGS TURBINE-DRIVEN UNIT

FIG. 2. STEAM-TURBINE-DRIVEN RETURN-LINE HEATING PUMP

pump designed for air, while the water is handled in a pump designed for water. This permits a much higher efficiency than in one pump handling both air and water.

The air end of the new turbine-driven unit is a development of the well-known Hytor vacuum pump, in which the rotor, the only moving part, revolves in an elliptical casing filled with water. The water turns with the rotor, but follows the casing, due to centrifugal force.

The water end of the machine is a centrifugal pump with an inclosed type impeller designed to give high efficiency when handling hot water. It has the very desirable characteristic of unloading when not handling condensation, and at the same time will require very little increased power when delivering against low heads. Provision has been made by special construction to vent the centrifugal inlet back to the receiving tank, which is under vacuum, precluding air binding.

All interior parts of the pump are constructed of bronze with the exception of the steam turbine rotor. No lubricant is required in the interior of the pump. No oil or grease can be introduced by the pump into the condensate. As the condensate is usually returned to a hot well, tank or feed-water heater for boiler feed purposes, this feature is very desirable.

The shaft upon which the impeller, rotor and steam turbine wheel are mounted is supported by the highest grade annular ball bearings mounted outside of the casing, in an adjustable housing. These bearings, if properly lubricated, will wear indefinitely.

The steam turbine rotating element consists of a solid steel forging with blades milled out off the rim.

A centrifugal throttling governor is furnished assembled as regular equipment to maintain a constant steam turbine speed. This governor automatically shuts off steam if the steam pressure rises or if the pump unloads when not handling condensation, preventing all increase in speed.

The turbines are designed to operate at 75 lb. steam pressure, although the turbine casing is suitable for steam pressures up to 200 lb. If it is desirable to operate at pressures lower than 75 lb., a satisfactory operation can be secured on pressures as low as 40 lb.

These pumps are ready for delivery in sizes up to 300,000 sq.ft. of equivalent direct radiation.

Synopsis of Recent Chemical & Metallurgical Literature

Chemical Research in India.—Dr. E. R. Watson, in charge of the Government Research Institute at Cawnpore, India, discusses chemical research for the development of industries in India in the *Journal of Indian Industries and Labour* for May, 1921. He points out a number of important manufactured articles which are not made at present in that country, notwithstanding the fact that the natural raw materials are present in abundance. Among such materials and articles are mentioned: zinc, copper, tungsten and other ingredients of high-speed steels, chromium, graphite, thorium salts for gas mantles, caustic soda, benzene and related products, rubber goods, tin plate, paper, drugs, dyes and essential oils. It is remarked that "in the absence of any means for production from purely Indian sources of sulphuric, nitric and hydrochloric acids and the alkalis, our manufactures, actual or prospective, of paper, drugs, matches, oils, explosives, disinfectants, dyes and textiles are dependent upon imports, which under war conditions might be cut off, yet sources of raw materials for heavy chemicals are not deficient."

The quantity of coal tar available at present in India is not sufficient to supply a large byproducts industry; about 500,000 tons of coke and 8,000 tons of tar are produced annually. Her production of coal is now 20,000,000 tons, which would indicate that the output of coke can be increased materially.

The Indian Government is interesting itself in a proposal to erect zinc-smelting works at Jamshedpur to handle zinc concentrates from Burma. The plant under consideration will deal with 25,000 tons of concentrate annually, producing 10,000 tons of spelter and 32,000 tons of sulphuric acid. This is practically equal to the consumption of sulphuric acid, practically all of which at present is imported.

Reduction By Sodium Hydrosulphide.—In two papers in the June number of the *Journal of the Chemical Society* ("Reduction of Emulsified Nitro-Compounds, Part I. Phenylhydroxylamine From Nitrobenzene," by Arthur Lapworth and Lenore Kletz Pearson; pp. 765-768; "Part II. Some Extensions of the Method," by Robert Downs Haworth and Arthur Lapworth, pp. 768-777) is described a method of reduction of nitro-compounds of great theoretical interest and of probable commercial value. The active reagent is sodium hydrosulphide (NaHS) in aqueous solution, prepared by acidifying sodium sulphide with the requisite quantity of hydrochloric acid.

The reduced compounds desired are the substituted hydroxylamines.

The sodium hydrosulphide acts as the reducing agent. As practically all nitro-compounds are insoluble in water, it was deemed necessary to emulsify the nitro-compound (liquid) or to dissolve it in a solvent like benzene or toluene (solid compounds) and emulsify the solution. Calcium chloride proved a very satisfactory emulsifying agent, as its addition caused the precipitation of a finely-divided precipitate of calcium hydroxide or "basic" calcium sulphides, in the presence of which emulsification readily occurred. Furthermore, the concentration of hydroxyl ions was probably regulated by the calcium ions present, so that the reduction proceeded chiefly in the direction desired. By regulating the concentration of the solutions it was possible to obtain the phenylhydroxylamine crystallized out from the solution at the end of the reaction. The crystals were contaminated by the precipitate of calcium compounds which catalyzed the oxidation of phenylhydroxylamine (to nitroso-benzene) by the air when filtered. This was minimized by adding ammonium chloride at the end of the reaction to dissolve the calcium compounds and filtering

off the relatively pure phenylhydroxylamine. On a large scale the ammonia could be recovered from the mother liquors, or probably better still, hydrochloric acid could be used to dissolve the calcium precipitate. As the reaction mixture absorbs oxygen from the air rather rapidly, the reaction would best be carried out in a closed vessel to reduce this oxidation.

Yields of 72 to 74 per cent of β -phenylhydroxylamine from the nitrobenzene used were obtained without counting what was left in the mother liquors and might be recovered in a continuous commercial operation. The raw materials, nitrobenzene, calcium chloride or hydrochloric acid, are sufficiently cheap to be used as commercial raw materials for the process if sufficient use for phenylhydroxylamine could be found.

p-chloronitrobenzene gave 68 per cent of the theoretically possible *p*-chlorophenylhydroxylamine.

p-bromonitrobenzene gave 65 per cent of the theoretically possible *p*-bromophenylhydroxylamine.

p-iodonitrobenzene gave 64 per cent of the theoretically possible *p*-iodophenylhydroxylamine.

p-nitrotoluene in benzene gave 53 per cent of the theoretically possible *p*-tolylhydroxylamine and a further 5 per cent could be extracted from the mother liquors.

o-nitrotoluene gave 15 per cent of the theoretically possible *o*-tolylhydroxylamine, which, however, did not separate out as such, but was estimated by oxidation to *o*-nitrosotoluene.

o-chloronitrobenzene gave 62 per cent of the theoretically possible *o*-chlorophenylhydroxylamine, which was not isolated as such, but was oxidized to *o*-chloronitrosobenzene, a new compound.

m-bromonitrobenzene gave 55 per cent of the theoretically possible *m*-bromophenylhydroxylamine.

m-chloronitrobenzene gave 57 per cent of the theoretically possible *m*-chlorophenylhydroxylamine.

α -nitronaphthalene gave close to 80 per cent of α -naphthylhydroxylamine. By using an excess of sodium hydrosulphide, and kieselguhr instead of calcium chloride (as calcium chloride emulsions break down on heating) and heating on water bath for eight hours, 73 per cent of theory of α -naphthylamine was obtained. At lower temperature with calcium chloride not a trace of α -naphthylamine was obtained.

α -nitroanthraquinone yields more than 80 per cent of theory of α -aminoanthraquinone or 73 per cent of theory of α -hydroxylaminoanthraquinone, depending on conditions of experiment.

m-dinitrobenzene gave 3:3' dinitroazoxybenzene and 2:4 dinitrotoluene gave 3:3'-dinitro-4:4'-dimethylazoxybenzene as the partial reduction products.

Nitroanilines reduced by this method do not stop at the hydroxylamine stage, but reduce completely to the diamine stage.

p-nitrophenol gave no reduction products by this method.

(The abstractor may record that it is his experience that calcium chloride is a useful catalyst in reductions of nitro-compounds. Thus, *p*-nitraniline is almost quantitatively smoothly reduced to *p*-phenylenediamine by zinc dust in the presence of calcium chloride in aqueous solution. The application of sodium hydrosulphide to reductions is by no means new, although its application to emulsified insoluble nitro-compounds is original and useful. Hundreds of thousands of pounds of *m*-dinitrobenzene have been reduced to *m*-nitraniline by means of sodium hydrosulphide, but, as shown in the paper quoted, the intermediate reduction to the hydroxylamine is impossible in this case under the given conditions.)

Proof Loads.—After remarking upon the fact that many engineering materials do not possess any "yield point" when testing in tension and that the determination of the elastic limit, proportional limit or fatigue limit is not now a practicable operation in routine testing, an editorial writer in the *Engineer* for July 8, 1921 (p. 42), goes on to say:

"Fortunately, a fairly satisfactory alternative exists and has been incorporated in some of the recent specifications of the British Engineering Standards Association. It is the specification of a 'proof load.' There may be some doubt as to the appropriateness of this particular term, but the idea itself appears to be entirely sound. It is based upon

the principle that, instead of endeavoring to ascertain in the course of a rapid tensile test at what particular stress permanent deformation occurs to a measurable extent, it is better to decide beforehand, as the result of accurate tests made by means of extensometers or otherwise, what stress satisfactory material of that particular type should be well able to bear without undergoing any extension more than a small specified amount, such as $\frac{1}{2}$ per cent. If the figure thus arrived at is specified as the 'proof load,' it is a very simple matter to test any given specimen. All that need be done is to mark the test-piece accurately with two fine lines whose distance apart is the standard specified gage length; the specified 'proof load' is then applied to it for a specified short time and the load is then removed and the test-piece remeasured. If the lines marked on it have not moved apart by more than the specified amount— $\frac{1}{2}$ per cent—the test has been passed, and the breaking or ultimate stress, extension, etc., can then be determined by a further test on the same test-piece. It is all very simple and quick; measuring appliances, such as small microscopes, can easily be mounted so that the measurement can be made in a few seconds without removing the test-piece from the machine. Above all, however, is the great advantage that the manufacturer, the inspector and the engineer all obtain a definite determination which bears some relation to the properties of the material, instead of a vague estimate of a non-existent yield point."

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Acid-Resisting Alloy.—Foster Milliken, of Lawrence, N. Y., has prepared an alloy with a high resistance to corrosion by acids and capable of withstanding high temperatures. It is claimed to be serviceable for use in the manufacture of plugs and other still fittings. Its approximate composition is as follows: Copper, 45-55 per cent; nickel, 29-35 per cent; lead, 1-3 per cent; zinc, 5-9 per cent; iron, 4-8 per cent; and silicon-copper (approximately 10 per cent) 1-3 per cent. (1,377,089; assigned to Foster Milliken, S. F. Deaver, and James M. Repplier, trustees; May 3, 1921.)

Manganese-Magnesium Alloy.—Magnesium and manganese, when heated together, do not ordinarily alloy to an appreciable extent except at temperatures above the boiling point of magnesium. If, however, there is an inter-fusing of a limited amount of a manganese compound, such as manganous oxide or chloride, with an excess of magnesium, it is possible to obtain an alloy of manganese with magnesium in the proportion varying from 0.5 to 8.0 per cent. These alloys, with specific gravity of less than 2, have an ultimate strength of more than 20,000 lb. per sq.in. when in the form of castings. (1,377,374; WILLIAM R. VEAZNEY, assignor to the DOW CHEMICAL CO., of Midland, Mich.; May 10, 1921.)

Refining Sulphur.—In the mining of sulphur in Louisiana and Texas, the melted sulphur is brought to the surface and diverted to wells or sumps, where it is permitted to cool and solidify. The solidified sulphur is then removed and broken into fragments of suitable size for shipment. The process is long and there is a considerable production of fines which are more or less undesirable. Raymond F. Bacon and Calvin H. Wenrich of Pittsburgh, Pa., have patented a substitute process by which the molten sulphur is converted into pellets and similar pieces of size and weight which may be uniformly controlled by the operator. This is accomplished by supplying the sulphur, at a temperature of 115 to 130 deg. C. in the form of drops into a solution of a salt, such as calcium chloride, in water. The solution contains sufficient salt to give it the required

specific gravity as well as a sufficiently high boiling point. (1,378,084; assigned to TEXAS GULF SULPHUR CO., Bay City, Tex.; May 17, 1921.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Gas Manufacture.—In a plant for the distillation of carbonaceous material by contact with hot producer gas, a number of producers are used to consume the whole of the coke obtained, and only one producer delivers gas to the retort so as to avoid undue dilution of the coal gas prior

to the separation of tar oil. The coal is fed into a rotary retort *c*, and the coke is discharged through an annular casing *d* to a conveyor *f* feeding the producers *p₂*, *p₃*, *h*. The gas from the producer *h* passes through the retort to a condenser *j* and oil washer *k* and thence to an ammonia washer *m*, to which the gas from the auxiliary producers *p₂*, *p₃* is led directly by a main *n*. (Br. Pat. 162,459. H. Nielsen and J. R. Garrow, both of London; June 22, 1921.)

Refuse-Consuming Furnace.—A vertical shaft refuse destructor comprises a device for collecting the noxious fumes, etc., means for heating air for combustion, and improved discharging means. The hopper 1 is closed by a cone-valve 2 mounted on a movable sleeve 3 operated by chains 8. Concentric with the sleeve 3 is a tube 5 serving as an escape flue for fumes and distillation products. Refuse is distilled and dried in the upper zone *A* and is then consumed in the lower zone *B* with air which is heated in two annular passages 17, 19 and vertical ducts 18 and downwardly discharged by orifices 16 into an enlarged cone-shaped lower portion of the shaft. The residue is discharged by segmental drums 23 consisting of hollow air-cooled disks mounted on horizontal rotatable shafts. Orifices 21, 22 admit steam jets or other means for disintegrating the clinker. Flames escape by a suitable duct and may be used for steam generation etc. (Br. Pat. 162,597. H. Breuille, Paris; June 22, 1921.)

Arsenical Compounds.—Salts of thioarsenic acids, possessing the general formulae $RA_3O_3 \cdot xS_x$ and $R_3AsO_4 \cdot xS_x$ in which R represents an alkali metal, ammonium or an organic ammonium radicle, are prepared by passing sulphuretted hydrogen into a solution of an arsenate, or by treating arsenious oxide or arsenic trisulphide with an alkali or ammonium polysulphide, or by treating arsenic pentasulphide with an alkali or ammonium monosulphide, followed by double decomposition in the case of the organic compounds. Examples are given of the preparation of $Na_3AsO_3 \cdot 12H_2O$, $Na_3AsO_3 \cdot 10H_2O$, $Na_2AsO_3 \cdot 10H_2O$, $Na_3AsS_4 \cdot 8H_2O$, $NaAsS_4$, and of the analogous salts of methyl-

amine and ethylamine. The substances are of use for the destruction of parasites externally. (Br. Pat. 162,747. K. B. Edwards, London; June 29, 1921.)

Casein Composition.—Casein is treated with formaldehyde, dried and shaped under heat and pressure. The casein may be coarsely or finely ground and moistened with a solution of formaldehyde, or the unground casein may be soaked in the solution. The drying is preferably continued until no trace of free aldehyde remains. The material is moulded at a temperature above 90 deg. C. and a pressure exceeding 100 atmospheres. (Br. Pat. 162,657; not yet accepted. E. Krause, Berlin, and H. Blücher, Leipzig; June 22, 1921.)

Treating Poor Iron Ores.—In the treatment of poor iron ore containing weakly magnetic or non-magnetic oxygen compounds of iron by subjection to a reducing roast at about 400 deg. C. to facilitate magnetic separation, the concentration is effected while the material is still in the reducing atmosphere. The ore is fed to helical channels 2 in a rotary furnace having a central heating-passage 24. Hydrogen is supplied to the channels through a pipe 3, and the gaseous products escape through a pipe 4 to a condenser. The magnetic separator comprises a cylinder 5 which rotates with the furnace, and is partly surrounded by a system of magnets 6. Helical ribs 10 convey the material into the magnetic field, and the particles attracted to the surface are

carried to the top, fall into a stationary pocket 7, and are conveyed to an outlet 19; non-magnetic particles are discharged through an opening 20. In a modification, the separation is effected in the furnace itself, and the magnetic and non-magnetic particles after separation are conveyed automatically into one or other of the two helical channels. The reduction of the magnetic material may be completed, and the product melted in an electric or other furnace. (Br. Pat. 162,718. R. Stören and R. Johanson, both in Norway; June 29, 1921.)

Recarburizing Steel.—A means for recarburizing molten steel in an open-hearth furnace consists of a box *a* which is carried on a ram *c* and fitted with hopper-like plates *a*⁴, *a*⁵, to contain the carbonaceous material, and provided with an extension *a*⁶ to pass through the slag. The extension is temporarily closed by a cover, such as a wooden plug *d*, adapted to be melted or consumed in the molten steel. The openings *a*⁷ between the plates and the extension are temporarily closed with paper stoppers, and a vent *a*⁸ is provided to allow the escape of gas generated during the operation. (Br. Pat. 162,994. J. N. Kilby, Rotherham, and N. H. Bacon, Sheffield; June 29, 1921.)

Making Tungsten Wire.—In making tungsten wire, particularly for electric-lamp filaments, a blank consisting of rods which contain or are bound together to produce in their cross-section zones differing from one another as regards their composition in physical properties is drawn and then submitted to a heat-treatment so that the crystals form uniformly along the length of the wire. The length of the crystals in the direction of the axis of the wire exceeds the diameter of the wire several times. The blank may differ in composition from the axis to the circumference or from side to side, or may contain different sectors. The blank may consist of a casing into which circular, rectangular or other structures of desired composition are inserted, the casing or core consisting of pure tungsten, tungsten and thorium oxide, or tungsten alloyed with metals or metalloids such as molybdenum, manium, thorium, tantalum, vanadium,

chromium, carbon or phosphorus or mixtures or compounds thereof or with other elements dissolved or admixed therewith. As examples, the casing may consist of pure tungsten and the core of tungsten containing thorium dioxide, or the casing may be of tungsten containing thorium dioxide and the core of pure tungsten or tungsten containing a small quantity of thorium dioxide. The thorium oxide, etc., may be introduced into the blank by superposing or imbedding or introducing into holes in the blank layers of powder, by inserting sintered or mechanically worked bodies or by saturating with solutions. The wire may be regularly heated throughout its whole length or may be heated by passing the wire through a hot zone. The latter method may be effected by heating sections of the wire in turn by an electric current or by surrounding with a hot cylinder or ring. (Br. Pat. 163,014; not yet accepted. Patent Treuhand Ges. für Elektrische Glühlampen, Berlin; June 29, 1921.)

Separating Water From Coal Tar.—Water is separated from coal tar by projecting the tar upwardly against a

separating surface to which the water adheres and from which it is collected. A vessel *a* is provided with a container *b* having conical ends *b*², *b*³, the end *b*² preferably having a tube *c* and the end *b*³ being open to the vessel *a*. The vessel *a* is filled with tar which enters and is heated by a coil *d* in the container *b*, and the tar is projected upwardly against an inclined separating plate *e*, the water adhering to the under surface of the plate and traversing along until it creeps over the upper edge. A drain pipe *f* is provided above the lower end of the plate *e*. (Br. Pat. 163,011; not yet accepted. Bismarckhütte, at Bismarckhütte, Upper Silesia; June 29, 1921.)

Cellulose and Other Carbohydrate Ethers.—In the production of ethers of cellulose, starch, dextrine, etc., their conversion products and derivatives, the cellulose, etc., is before reaction with the alkylating, aralkylating or arylating agents, treated with solid caustic alkali either in the dry state or in the presence of so little water or caustic alkali solution that at least a part of the caustic alkali remains undissolved; the products—films, celluloid, artificial filaments and insulating materials—prepared from the ethers eventually obtained, are distinguished by their water-resisting properties. The incorporation of the cellulose, etc., with the caustic alkali may be conducted in the presence of air or inert gas, or in vacuo, and at ordinary temperatures, or with heating or cooling; and the treated cellulose may before etherification be freed wholly or partly from the water contained therein, and may be immediately treated with the alkylating, etc., agent, or after standing. The etherification may be conducted so as first to form a lower ether, which may be converted into a higher ether by treatment with further quantities of caustic alkali and alkylating etc. agent. (Br. Pat. 163,018; not yet accepted.—See also 163,016 and 163,017.—L. Lilienfeld, Vienna; June 29, 1921.)

Calcium Nitrate.—Calcium nitrate is obtained from nitric acid obtained from atmospheric nitrogen by concentrating the acid to about 48 deg. Bé. and supplying ground calcium carbonate (limestone) and the concentrated acid continuously to an apparatus in which the temperature is not allowed to rise above the boiling point of the acid, 60 to 80 deg. C. being mentioned. The apparatus may consist of a horizontal tube having a conveying screw which discharges the calcium nitrate in a pasty condition. The carbonic acid is withdrawn under reduced pressure at the end at which the reagents are supplied. (Br. Pat. 163,330; not yet accepted. Aluminum Industrie Akt. Ges., Neuhausen, Switzerland; July 6, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Chemical Schedule Considered

After closing the public hearings on the dye embargo, the Finance Committee of the Senate began listening to testimony in regard to the various items in the chemical schedule and items on the free list which would fall within that schedule if made dutiable.

Producers of salt told the committee that after many years, during which no efforts were made to import salt, large quantities now are arriving at north Atlantic ports from Germany. Due to lower producing costs and to low ocean rates, salt from Germany is being offered at Atlantic ports at 29c. per 100 lb., it was testified. This is less than the average freight rate from the mines in New York State. The Fordney bill carries a duty of 7c. per 100 lb. This is held by the domestic producers of salt to be entirely inadequate. They ask for a duty of 15c. per 100 lb., plus an ad valorem rate of 20 per cent. The ad valorem rate is contingent upon American valuation.

The National Association of Glue and Gelatin Manufacturers appeared to ask for a segregation of glue and gelatin. It was pointed out that gelatin is a much higher-grade product than glue and should not be grouped with it under one bracketing and rate. The association of glue and gelatin manufacturers has asked that paragraph 39 of the bill be corrected so as to read:

Glue, and glue size, 20 per cent ad valorem and 1½c. per lb.; manufactures, wholly or in chief value of glue, cascin glue, isinglass and other fish sounds, cleaned, split or otherwise prepared, and agar agar, 25 per cent ad valorem. Gelatin conforming to United States pure food laws specifications, 20 per cent ad valorem and 7c. per lb. Technical gelatin, gelatin in sheets, or otherwise, with physical qualities to show a solidified jelly in mixture of 1.8 g. of gelatin to 100 c.c. of water at 42 deg. F., for six hours, valued above 30c. per lb., 20 per cent ad valorem and 15c. per lb. Manufactures, wholly or in chief value of gelatin, 35 per cent ad valorem.

August Kochs, president of the Victor Chemical Works of Chicago, addressed the committee with regard to oxalic and formic acids, asking that a specific duty of 5c. per lb. be allowed in addition to the 25 per cent ad valorem rate contained in the bill passed by the House. He said the American industry has been struggling to live for fifteen or eighteen years and that the rate of duty asked is necessary for the continuation of the industry.

Don D. McCloud, representing the Gas Products Association, which is composed of forty manufacturers of oxygen, appeared to protest against a duty of \$20 a ton on calcium carbide.

Matthew Adgate, representing the Naugatuck Chemical Co., of Naugatuck, Conn., protested against a rate of 6c. per lb., and 30 per cent ad valorem on acetaldehyde and paracetaldehyde. He pointed out that these chemicals are not manufactured in the United States and are important in the rubber industry.

R. L. Hoguet, president of the Antimony Compounds Co., of New Brunswick, N. J., told the committee that the Fordney bill rates of 2c. on antimony oxide and 1½c. on antimony are inadequate. He suggested that a duty of 4c. on each would be necessary in order to equalize the lower labor costs in China.

John H. Keusel, of Tenaflly, N. J., president of the Meadows Oil & Chemical Co., asked that the Fordney bill be revised so as to protect American manufacturers against synthetic ammonium ichthyolate.

J. G. Timolate, representing the Oakland Chemical Co., New York, urged the committee to remove the duty on crude barytes or at least not to allow it to exceed \$2 per ton.

A representative of the Commercial Solvents Corporation presented an argument in behalf of a duty of 20c. per lb. on amyl, butyl and isopropyl alcohols and fusel oil. These alcohols are made dutiable at 6c. per lb. in the bill passed by the House.

Nine manufacturers of epsom salts presented a brief and oral argument asking that 35 per cent ad valorem be added to the ½c. duty on epsom salts allowed in the Fordney bill.

Charles B. Grimes, representing importers of bone black, appeared in opposition to the 20 per cent duty contained in the House bill. He said it would prohibit all importations.

A representative of the Diamond Match Co. urged that phosphorus be put on the free list. The rate in the Fordney bill of 10c. per lb. will put the domestic match industry at the mercy of a company controlled in England, he said.

The committee on magnesite consumers, a representative of the American Refractories Co., of Pittsburgh, and a representative of an American company engaged in magnesite mining in Venezuela, presented arguments intended to convince the committee that crude magnesite should be put on the free list.

Bill to Stimulate Production of Mineral Raw Materials for Chemical Industry

With Congress prescribing particularly high rates of duty to foster the chemical industry, Representative Rhodes, chairman of the House Committee on Mines and Mining, believes the Government should undertake a comprehensive program looking to the stimulation of the production of non-metallic minerals from which the chemical industry draws much of its raw material. It is Mr. Rhodes' intention to concentrate his efforts toward getting such action. He is assured of the unanimous support of the Committee on Mines and Mining.

As the first step of this program, Mr. Rhodes has introduced the following bill:

That the United States Bureau of Mines be authorized and directed to carry on investigations as follows:

(1) To conduct inquiries and scientific and technical investigations in the United States and its territories concerning the mining, treatment and utilization of non-metallic minerals, such as sulphur, phosphate rock, feldspar, potash, mica, graphite, talc, barytes, limestone, and so forth, with the main object of elimination of waste both in their production and utilization.

(2) To conduct investigations for the purpose of aiding in the efficient production of the non-metallic and other mineral raw materials for the chemical industry, and to investigate and obtain fundamental data needed for the efficient production of chemical products from mineral sources.

Mr. Rhodes points out that no other industry was developed during the war to the same extent as was the chemical industry. A natural complement of tariff protection for the industry is the stimulation of the production of such domestic raw materials as that industry can utilize, Mr. Rhodes believes. He contends that the development of the non-metals has lagged far behind that of the metalliferous minerals. As evidence of that contention, Mr. Rhodes points to the action of Congress during the war in authorizing an appropriation of \$50,000,000 in an effort to stimulate the prompt production of a number of minerals then urgently needed for war purposes. Among them were about forty non-metals.

"Now that the war is over," he says, "we are content to settle back comfortably and allow ourselves to follow the line of least resistance and continue to buy our non-metals from foreigners. When the country needed these minerals most, we found that they were undeveloped. We have had our lesson. Now there is no excuse for our failure to achieve economic independence in practically all of the non-metals."

The Muscle Shoals Situation

Since the defeat of the appropriation for continuation of the work on the Wilson dam there has been a feeling on the part of some of the friends of that project that the Muscle Shoals development is enmeshed hopelessly in politics and misunderstandings. There is a growing impression, however, that Henry Ford's proposition offers a way out. While several propositions were submitted in response to the request of the Chief of Engineers, there was but one practical proposal—that of Mr. Ford. The other propositions were indefinite and unaccompanied by any evidence that the persons submitting them commanded financial resources necessary to carry on the work.

J. B. Duke, president of the Southern Power Co., is understood to have expressed the opinion that the Government cannot complete the Wilson dam and the hydro-electric plant and obtain a reasonable return on the investment. His opinion, which is subscribed to by all the Southeastern hydro-electric companies except the Alabama Power Co., is understood to have been based on a report made by W. S. Lee, chief engineer of the Southern Power Co.

The Alabama Power Co. is not in a position to submit a bid at this time. Thomas W. Martin, president of the company, in reply to an inquiry by General Beach, Chief of Engineers, has explained the position of that company in a detailed statement.

It is believed that the business depression prevented some interests from submitting bids. Had times been better, much more interest would have been shown in General Beach's inquiry, it is believed. The inquiry was sent out widely to interests likely to be able to make use of this power. Some interests, it is stated, entered upon a systematic effort, when the appropriation failed of passage, to belittle the whole Muscle Shoals proposition. As a result, they were not in a position to reverse themselves by submitting bids.

Considerable criticism is reaching Washington as a result of the action of the Secretary of War in making public the Ford proposal. This gives an unfair advantage to other bidders, it is declared, and is contrary to the long-established policy of the War Department.

There can be no doubting of the widespread and growing public demand that the Ford offer be accepted unless some one else is willing to submit a better proposition at once. This is evidenced by the large number of letters which are being received from all sections of the country by Senators and Representatives. The publicity the matter has received has also had the effect of arousing new demands that the Government itself undertake the operation. Senator Underwood continues to insist that the operation of the project by the Government is the only way in which the public will receive the maximum benefit from this natural resource. It is believed that he will support legislation looking to the carrying out of the Ford proposal, or any other private proposal, only when he is convinced that the opposition has the votes to defeat Government operation.

Some letters are being received on Capitol Hill alleging that Mr. Ford is seeking this resource as a part of his plan to monopolize the farm tractor and cheap automobile fields. This charge, it may be said, is not regarded seriously by legislators, as it is generally recognized that such monopoly as Mr. Ford's products may enjoy has not been obtained by absorbing competitors, but by attaining costs so low that competitors are not able to compete.

Byproduct Coke Oven Company Formed

The Belgian-American Coke Ovens Corporation, New York, has been formed with a capital of \$10,000,000, to construct and install Piette byproduct coke ovens and carbonization equipment for fuel saving. Olivier Piette, of Belgium, holds the patent rights to the coke ovens and appliances, and will be on the board of directors of the new organization, which is headed by Thomas F. Ryan and F. S. Landstreet, both of New York. The latter has been elected president of the company and offices have been established at 25 Broad St. The American corporation will have the assistance of technical experts from Belgium. The European organization is known as the Franco-Belgian Coke Ovens Corp.

Salesmen's Association of American Chemical Industry

One hundred representative salesmen and sales executives connected with American manufacturers and their recognized sales agents in all branches of the chemical industry will be invited to become charter members of the Salesmen's Association of American Chemical Industry, after plans of the organization committee have been formed.

This committee, which consists of Fred E. Signer of Butterworth-Judson, chairman, Charles F. Abbott of National Aniline, John A. Chew of Warner Chemical Co., P. S. Tilden of du Pont, A. H. Pierce of Grasselli, E. J. Barber of The Barrett Co., E. C. Scott of Wing & Evans, and Williams Haynes of Drug & Chemical Markets, secretary, held a meeting Monday, Aug. 8, at which a constitution was drawn up. This constitution provides that the membership shall be open to any American citizen connected with the sales or advertising staff of an American chemical manufacturer, or his recognized sales agent, and vests the active control of the association in an executive committee, consisting of the officers and six members, two of whom shall be elected every year to serve three years and who shall be ineligible for re-election at the expiration of their term. The committee is considering plans for the promotion of local associations in the various large cities.

According to the present plans, invitations will be extended to one hundred thoroughly representative salesmen to join as charter members. Details are being considered for a meeting and dinner to be held at the time of the Chemical Exposition.

Salesmen interested in this organization, the object of which is to be the fostering and promotion of the commercial interests of the sales staffs and of the broader interests of the chemical industry as a whole, are requested to communicate with the secretary, 3 Park Place, New York City.

Wants Organic Chemistry Encouraged

Senator Ladd, of North Dakota, appeared before the Senate Finance Committee as a witness to make a special plea for an American organic chemical industry. He classed the making of dyes as a master-key industry and declared that he would rather see a monopoly than to take any chances on destroying the start which the United States has made in the manufacture of dyes. Senator Ladd's statement to the committee follows:

I simply desire to come before the committee and record my interest in American organic chemistry and the chemical industry in this country. For nearly forty years I have been engaged as a researcher and chemist, and in chemical laboratories as a teacher. I have seen in the past the need of building up organic chemistry, which has not been made possible because of the fact that the Germans had apparently complete control of the manufacturing.

I feel that if England and France and Italy and Japan found it necessary to place an embargo on dyes for a certain length of time, those that are made in those countries, and to afford protection to those that are needed to build up, the United States ought to do the same thing. I do not feel that it is likely that a tariff, however high it may be placed, will enable the organic chemical industry of the country to develop as we hope for.

I have heard considerable and read considerable on the question of a monopoly in the dye industry. I doubt very much that that is true in any true sense of the word, but if there is to be a dye monopoly I would rather see it in the hands of American manufacturers, where they can be controlled by Congress and the American people, rather than in the hands of foreigners. I think we can render a distinct service at this time to chemistry and to the industries of this country by protecting the organic chemical industry and the dye industry, to furnish means of training our young men who are graduates of educational institutions in chemistry for work along the lines and in the lines necessary for development in this country. If we are to be drawn into another war at any time it seems to me that we will be in a very poor condition unless our organic chemistry and our institutions for manufacturing organic materials of all classes are well protected.

Chemical Exposition Notes

PUMPS AND CONDENSERS

Air pumps and condensers have not been overlooked at the chemical exposition this year. A most comprehensive exhibit has been planned as part of the annual show, which will be held in the Eighth Coast Artillery Armory, New York, Sept. 12 to 17. One company will display besides a double effect evaporator with circulating pumps and piping, a barometric ejector condenser, a centrifugal pump, Edwards air pump, and two steam jet air pumps, a model cooling tower tube exhibit.

Pumps for air, industrial gas or acid gas will be exhibited. A pump or compressor where no valves, gears, pistons, piston packing, sliding vanes or interior lubrication is necessary will be entered in one of the displays on this subject. Tank pumping installations, pumping systems, vacuum apparatus for all chemical purposes, dry vacuum, centrifugal, air compressors, acid, and hydraulic pressure pumps and deep well engines will be shown. Hard rubber pumps, pipe, fittings, tanks and utensils will form part of this most complete exhibition.

International Conference at A. C. S. Meeting

The fall convention of the American Chemical Society will be opened by a general meeting to be held in the gymnasium of Columbia University, Wednesday, Sept. 7, at 10 a. m. Sir William J. Pope will speak and Herbert Hoover has promised to address the gathering provided public duties do not interfere.

On Thursday, Sept. 8, a joint international meeting will be held in the Great Hall of the College of the City of New York. Dr. Edgar F. Smith will preside. The following addresses have been announced:

"Science and Civilization; the Rôle of Chemistry," by Prof. Charles Baskerville.

"Energy; Its Sources and Future Possibilities," by Dr. Arthur D. Little.

"The Engineer; Human and Superior Direction of Power," by Dr. Leo H. Baekeland.

"Chemistry and Life," by Sir William J. Pope.

"Theories and Their Development," by Dr. Willis R. Whitney.

"Research Applied to the World's Work," by Dr. C. E. K. Mees.

"Problem of Diffusion and Its Bearing on Civilization," by Prof. Ernst Cohen, of the University of Utrecht.

"Catalysis; The New Economic Factor," by Prof. Wilder D. Bancroft.

Prof. Samuel A. Baldwin, head of the department of music of the College of the City of New York, will give an organ recital in honor of the delegates.

Following the sessions at Columbia University the chemists will attend the National Exposition of Chemical Industries, which is to be held from Sept. 12 to 17, inclusive, in the Eighth Coast Artillery Armory in the Bronx. At this exposition will be shown many new types of chemical apparatus and of machinery used in the large-scale manufacture of the products of industrial chemistry.

Optical Society to Meet in Rochester

The Optical Society of America will meet in Rochester, N. Y., Oct. 24, 25 and 26 at the Hotel Rochester. Members and others desiring to communicate results in optical research are invited to submit titles any time before Sept. 25 to the secretary, Irwin G. Priest, Bureau of Standards, Washington, D. C. Because of the optical industries in Rochester it is expected that this will be a particularly interesting meeting. The local committee is arranging for visits to Bausch & Lomb and the Eastman Kodak Co.

British Chemical Workers to Strike

According to a recent cable despatch from London, the executive committee of the Federation of Chemical Workers has rejected the employers' proposal to reduce wages 2d. per hour. The men propose to strike on Aug. 27. The Brunner Mond Co. threatens to close down its Winnington works unless sufficient men accept the reduced wage and agree to continue under the new scale.

Alcohol Fumes Explode at Abbott Laboratories

The Abbott Laboratories, large manufacturer of synthetic pharmaceuticals, had a serious explosion in the process plant at 4753 Ravenswood Ave., Chicago, on Monday, Aug. 8. One of the operations involves the production of high proof alcohol in an apparatus consisting of a Stokes rotary vacuum drier, a dust trap and distillation column. The horizontal drier, 15 ft. long by 3½ ft. diameter, with steam jacket and horizontal agitating mechanism, receives the mixture of slaked lime and low proof alcohol through an opening on top. The gasketed cover is clamped down and steam introduced in the annular space about the mixing chamber. No vacuum was used at the time of explosion and the steam is introduced at such rate that no pressure registers on the gage.

Alcohol vapor passes over through the dust trap, which is a horizontal steel cylinder about 2 ft. in diameter by 4 ft. long equipped with baffles for catching any lime dust which may be mechanically carried in the vapor. From this point the vapor is carried upward through a pipe bend (about 8-in. pipe) into the top of the column. The agitating shaft is driven by a 15-hp. four-pole direct-current back-gearred open electric motor, in turn controlled through an inclosed "Square D" knife switch and exposed starting box with release coil. All this apparatus is mounted on the frame at the end of the drier.

As near as can be determined the pipe bend between trap and column became clogged near the top of the still with lime dust, the dust trap having ceased to function. Pressure of entrapped alcohol and water vapor built up immediately in the inner chamber of the drier and began to leak into the room around the gasket at the feed opening. The operator, noting something was amiss, first shut off the steam supply leading to the jacket. By this time a considerable quantity of alcohol fume and water vapor had filled the room. He next pulled the electric knife switch and the explosion immediately occurred. Fire doors on the nearby elevator shaft and at the other side of the room about 50 ft. away were blown down and the windows were shattered. None of the woodwork was scorched and the rack of time cards a few feet from the switch had only one or two cards browned at the edges. Six operators were injured, three of them seriously burned. William Copeland, who pulled the switch, and Elmer Groskopf, standing near by at the time, both died in the hospital two days later.

It is apparent from the testimony of witnesses that the fumes were ignited by an electric spark incidental to the shutting down of the motor. This spark may have been furnished by the brushes on the motor commutator, by an arc on the knife switch or by the starter contact arcing as it passed over the segments. While the "Square D" knife switch is totally inclosed by a sheet iron case, the cover was not gasketed to prevent the permeation of explosive fumes.

Total gas-tight inclosure of all electrical apparatus in chemical plants handling flammable or explosive gases would do much to obviate such accidents, for it is not always possible to control fumes. The new process plant being erected by the Abbott Laboratories at North Chicago will have fireproof compartments and the electrical apparatus will be in separate chambers from the process machinery.

Ceramic Society to Visit England Next Year

At a recent meeting of the Glass Division of the American Ceramic Society a letter was received from Dr. Turner, head of the Society of Glass Technology of England, inviting the entire membership of the American Ceramic Society to attend the joint conference in England in 1922.

The American Ceramic Society is now soliciting its membership to ascertain how many members contemplate making this trip. They plan to leave the United States about Aug. 15 and remain in England about one month, visiting glass- and clay-working plants of the British Empire.

The itinerary covers a three weeks trip, including visits not only to glass works in different cities in England and Scotland but the china works and other industries at Derby and Stokes and the fireclay and material works at Stourbridge.

Brussels Meeting, International Union of Pure and Applied Chemistry

The 1921 meeting of the International Union of Pure and Applied Chemistry was held in Brussels from June 25 to 30, under the presidency of Prof. Charles Moureau, member of the Institut de France. At a preliminary meeting, the Council, composed of representatives of countries already admitted (see CHEM. & MET., vol. 23, p. 210), unanimously approved the admission to the Union of Argentina, Japan, Monaco, Norway, Portugal, Rumania, Switzerland, Uruguay and Jugoslavia. Eighty-two delegates from eighteen countries were present. Dr. F. C. Cottrell, Prof. C. Mackall and Prof. J. B. Conant represented the United States, while Great Britain sent Sir William Pope, Dr. S. Miall and Prof. T. M. Lowry. France had 26 delegates, Belgium 15, Italy 12, Netherlands 4 and Switzerland 4.

Further Council meetings and the general assembly were devoted largely to a discussion of the reports of committees appointed last year at the meeting in Rome.

COMMITTEE ON ATOMIC WEIGHTS

The existing International Committee on Atomic Weights is to be reorganized as the International Committee on Chemical Elements. It will consist of twelve members, divided into three sub-committees to deal with atomic weights, the compilation of a table of isotopes, and the constants of radioactive elements.

NOMENCLATURE

The report of the committee on nomenclature, adopted unanimously, recommends: (a) The formation of three international committees on nomenclature to deal with organic chemistry, inorganic chemistry and biological chemistry respectively. (b) The formation of three working sub-committees, of six members each, elected by the international committees, each member being intrusted with the task of forming, with the aid of his national federation, a national committee to discuss questions of nomenclature; the proposals put forward by a national committee to be embodied in a report for circulation among chemists of other nationalities.

CHEMICAL ABSTRACTS

The following recommendations relating to the unification of abstracts, put forward by the National Council of the Netherlands, were accepted: (1) That the Bureau of the International Union take the initiative in bringing together representatives of chemical journals that publish abstracts with a view to discussing the eventual formation of a central publication and its probable cost. (2) That the possibility of conducting an international chemical card index be investigated together with the approximate costs of establishing and maintaining it.

INTERNATIONAL INSTITUTE OF CHEMICAL STANDARDS

In order to avoid confusion, M. Timmermans recommended that the three sections of the International Institute of Chemical Standards be named as follows: Bureau of Physicochemical standards (headquarters at Brussels); Research Chemicals (headquarters in England); Department of Publications Concerning Industrial and Technical Products (headquarters in Paris).

CERAMIC PRODUCTS AND FUELS

The establishment of national and international laboratories for the study of ceramic products and fuels was approved. Laboratories for the investigation of refractories will be attached to the fuel laboratories as special sections.

INTERNATIONAL PATENTS

The committee on international patents was re-appointed for another year. A resolution was passed by the assembly to the effect that the institution of international patents is highly desirable and that the Union should take the initiative by calling a conference to consider the question.

Reports on bibliographical contractions, the mechanical standards, tables of constants, analyses of foodstuffs, and international hygiene were also considered. It was resolved that the next meeting of the Union be held in France.

Conditions in the Brass Industry

A recent survey of conditions in the brass industry, taking Waterbury, Conn., one of the largest centers of this character in the country, as a barometer, shows that the trend is upward, with greater plant activity and larger number of operatives engaged. The reports of the different important companies in this district, show the following:

The American Brass Co. is now giving employment to as many men as in 1914 and 1915, working on a basis of forty hours a week, instead of regular time of fifty-five hours, as obtained in the two previous years noted.

Scovill Mfg. Co., manufacturing both brass and copper products, is employing the same working force as in 1914, with curtailed running time making about 60 per cent of normal pre-war capacity.

The Chase Metal Works and the Chase Rolling Mills are giving employment to about one-third of the number of operatives as compared with a year ago.

The Waterbury Mfg. Co. is operating at about 50 per cent of normal at the present time.

The American Ring Co. is employing about 75 per cent of its normal working force, with curtailed time approximating thirty-two hours a week. One department at the mills is operating on a 45-hour weekly schedule.

The Randolph-Clowes Co. is giving employment to about two-thirds of its regular force under a 32-hour week, instead of normal 55-hour running time.

The Mattatuck Mfg. Co. is using 80 per cent of its normal number of employees, with running time from 60 to 70 per cent of the regular schedule.

The Waterbury Buckle Co. is operating on a full-time basis.

The Novelty Mfg. Co. is employing two-thirds of its regular working force on a 45-hour weekly running time basis.

Blake & Johnson, brass and iron hardware, are operating with about 75 per cent of the normal working force, four days a week.

Status of Japanese Chemical Industry

It is necessary to establish a large government laboratory where the necessary experts can be trained, says Dr. Takamatsu, Director of the Tokyo Industrial Laboratory, in an official bulletin, if Japan is to hold her own in developing her chemical industry.

Before the war, he writes, Japan had to import most of her dyes and chemicals, especially from Germany. During the war the law for the encouragement of the dyeing and chemical industries was passed and in 1916 the Japan Dye-stuff Manufacturing Co. was established. Though this company has done its best, lack of funds and of expert workers has hampered its activities and even last year the imports of dyes were very large. They are likely to be much larger this year, judging from prevailing conditions.

During the war numbers of dye works were started in various parts of Japan, but nearly all of them have disappeared since the depression set in. Those that still hold on are working on a very small scale, have no permanent plans of business, but are looking only to immediate profits. The chemical industry, which is of so much importance to Japan, cannot be developed on such narrow lines, and the assistance of the government in the direction already indicated is urgently necessary.

The Japan Dyestuff Co., it is reported, is contemplating the engagement of dye experts from Germany. Such a plan may also be adopted by other chemical works in the country, which feel the necessity of a thoroughgoing reform of the industry.

Joint Dye Committee Named

In an effort to work out some compromise in the dye embargo controversy, a joint committee representing the Finance Committee of the Senate and the Ways and Means Committee of the House has been designated to study the existing situation. The Finance Committee will await the recommendations of the joint committee before deciding whether or not it will replace the dye embargo in the tariff bill. Included in the joint committee's membership are members of the committees representing each side of the controversy.

Bureau of Soils to Continue Phosphoric Acid Experiments

Investigations by the Bureau of Soils in the matter of extracting phosphoric acid from phosphate rock by the application of heat are to be continued. The bureau has issued the following official notice in that connection:

With the installation of a new high-temperature oil-burning furnace at the experimental farm at Arlington, Va., the Bureau of Soils, United States Department of Agriculture, will continue investigations into the extraction of phosphoric acid for fertilizer from phosphate rock by the application of heat.

Experimental runs with an old furnace several months ago apparently demonstrated the practicability of the new method developed by department scientists of separating the phosphoric acid. The present commercial method is by the application of sulphuric acid to ground phosphate rock. It is not practicable for low-grade rocks and makes necessary the shipment of a large proportion of inert material with the phosphate. Early experiments in separation by heat were made with electric furnaces, but the expense seemed a serious obstacle to the introduction of the new method. It was found, however, that the petroleum-burning furnace could be made to do the work at much less expense. Experiments will be continued to establish methods which will permit the use of much phosphate rock which now goes to waste, and also to a material reduction in freight rates on commercial fertilizers.

Transportation of Poisonous Articles

The Interstate Commerce Commission has acted favorably upon the petition of the American Smelting & Refining Co. and has amended one of the paragraphs of the regulations covering the transportation of dangerous articles, as follows:

"Arsenic, paris green, arsenate of lead, calcium arsenate and all other strongly poisonous articles must not be offered nor accepted for shipment in bulk, but must be packed in strong and tight containers which will prevent sifting or escape of contents in transit, provided that sintered arsenical flue dust may also be shipped between plants in steel gondola cars equipped with suitable covers."

Complete Utilization of Southern Pine Waste

An invitation has been extended by Joseph H. Wallace & Co. to the chemists who attend the fall meeting of the American Chemical Society and others who may be interested, to visit the company's research laboratory at Stamford, Conn., where much work has been done on the complete utilization of Southern pine waste. The laboratory will be open to visitors on Sunday, Sept. 11. Stamford is one hour from New York on the New Haven road and the laboratory is ideally situated on Webb's Hill, about five miles north of the station.

New Brick to Be Tested

A new cinder cement brick, manufactured under a process invented by Sigurd Bo, at the plant of the Farmingdale Cement Brick Co., Farmingdale, L. I., will be subjected to a series of tests at Columbia University, commencing Aug. 29. It is claimed that the new brick is stronger, lighter and cheaper than any other kind now in use. It has been tested by the New York Bureau of Buildings, and its approval by the department depends upon the results of the tests at the University.

Extension of Temporary Dye Control

With the increasing possibilities that the permanent tariff bill will not become a law much before Jan. 1, the Senate Committee on Finance amended the bill which passed the House in the matter of extending the temporary control over dyes and chemicals so as to continue the present procedure until Jan. 1, 1922.

Officials of German Potash Syndicate to Visit U. S.

A recent cable from Berlin states that several delegates of the Kalisyndikat will sail from Germany for the United States in September. They will make a careful survey of the potash market in America.

Personal

GERALD C. BAKER, who is on the sanitary chemistry staff of the State University of Iowa, is working during the summer on the problem of water softening with the Barromite Co. of America, in Chicago.

NEIL C. BOWMAN, president of the Pocono Rubber Cloth Co., Trenton, N. J., gave an interesting address at a luncheon and meeting of the local Rotary Club, Aug. 10, on the subject of "Rubber Cloth." The talk covered features of manufacture, and dealt particularly with rubber cloth for the automobile industry.

Dr. ALFRED S. BURDICK has been elected by the board of directors of the Abbott Laboratories, Chicago, as president, to fill the vacancy caused by the recent death of Dr. W. C. Abbott.

E. DANA DURAND has been appointed chief of the newly created eastern European division of the Bureau of Foreign and Domestic Commerce. Mr. Durand was director of the Bureau of the Census from 1909 to 1913, and from 1903 to 1909 was connected with the Bureau of Corporations of the Department of Commerce and Labor, first as economic expert and later as deputy commissioner.

OTTO EISENSCHIML sailed on July 26 for a two months' visit to Austria, where he will attend to personal matters.

Dr. HERBERT E. FOOTE, of Dover, N. J., experimental chemist at the Picatinny Arsenal of the Government, near Dover, was hurt seriously while engaged at his work Aug. 12, covering certain experiments with the nitration of benzene. He was removed to the Dover General Hospital, and the fear is expressed that he will suffer the loss of one of his eyes. The explosion in the laboratory slightly injured Dr. Foote's assistant, Frank McPeck, but with no serious consequences.

A. P. GLOECKLER has resigned as chief chemist of the Tropical Paint & Oil Co., Cleveland, Ohio, and has accepted the position of superintendent of the paint department of the Acorn Refining Co., Cleveland, Ohio.

O. C. JOHNSON is leaving the employ of Swift & Co. to become instructor in chemistry at the Ewing Christian College in India. He sailed from New York on July 30, and will spend at least three years in India.

Dr. IRVING LANGMUIR, assistant director of the research laboratory of the General Electric Co., sailed for Europe Aug. 13 to attend the annual meeting of the British Association for the Advancement of Science to be held in Edinburgh, Scotland, Sept. 7 to 14. He will also attend a meeting of the Faraday Society in London on Sept. 28 and will be awarded the honorary degree of Doctor of Laws by the University of Edinburgh on Sept. 13. Dr. Langmuir will open the discussion on Molecular Structure at the British Association meeting. He will read a paper before the Faraday Society on "Chemical Reactions on Surfaces," and open discussion on that subject. During his stay he will visit a number of European countries on business. He is expected to be absent from the United States between two and three months.

Dr. R. B. MOORE of the U. S. Bureau of Mines is visiting the Western stations of the bureau.

WILLIAM N. PORTER, of the Chemical Warfare Service, has been promoted to the rank of major.

J. LEONARD REPLOGLE, president of the Vanadium Corporation of America and chairman of the Replogle Steel Co., recently returned from a trip to Europe, where he has been studying business conditions.

EARLE E. RICHARDSON, who has been instructing in analytical chemistry and physics for the past four years at the Massachusetts Institute of Technology, has been appointed to the position of research physicist under L. A. Jones at the research laboratories of Eastman Kodak Co., Kodak Park, Rochester, N. Y.

Lithopone Sales in 1920

The quantity of lithopone marketed during 1920 showed an increase of 14 per cent over the figure for the preceding year, according to the compilation of reports from the manufacturers which has recently been completed by the Geological Survey. Quantity, value and average selling price of lithopone marketed during 1919 and 1920 are shown in the following table. It will be noted that the figures for 1919 differ from those previously published by the Survey, but the explanation is that the earlier statistics were for the quantity of lithopone manufactured and not that which was marketed:

LITHOPONE MARKETING IN 1919-1920

	Quantity, Short Tons	Value	Average Selling Price
1919.....	78,365	\$10,218,850	\$130.40
1920.....	89,373	12,484,925	139.69
Increase.....	11,008	2,266,075	9.29
Percentage.....	14.0	22.2	7.1

Current Market Reports

Chemical and Allied Industrial Chemical Markets

NEW YORK, Aug. 22, 1921.

Some improvement in the demand has been noted in the heavy chemical field, although business is still limited to comparatively small lots. Prices all around are firmer, with a less pronounced tendency to shade except in instances where unusually heavy orders are in prospect. Advices from Germany that prices are somewhat firmer, especially in the alum group, have probably caused some stiffening in the New York market. Throughout the trade the feeling is decidedly better and all leading factors are looking forward to greatly improved business in the fall or early winter.

CHEMICALS

Buyers of *acetic acid* are not showing any inclination to come into the market and prices remain unchanged with makers' quotations ruling. The price basis is \$2.50@\$2.75 per 100 lb. for the 28 per cent and 10@10½c. per lb. for the glacial, although occasional small lots may be located in resale hands at lower figures. Buyers of *muriatic acid* are showing very little interest, and makers are unable to reduce prices to any further levels. Stocks are not excessive and producers are holding them down as low as possible. Quotations for the 20 deg. range from \$1.25@\$1.75 per 100 lb. in carload quantities. In spite of the recent sharp declines in nitrate of soda prices, *nitric acid* held steady at recently quoted figures. The demand has been of only a limited nature. Prices are quoted on a basis of 6½@7c. per lb. in carboys for the 40 deg. test in carlot quantities. Prices on *ammonia alum* are based on 3½@4c. per lb. for the lump, with imported and domestic goods competitive. *Potash alum* is offered by importers on a basis of 3¼c. per lb. for lump, against a domestic price of 5¼c. Cable advices from Germany state that an advance of 50 per cent has been made on alum prices. The announcement has not affected any spot prices, partly on account of the recent decline in the exchange. Quotations on *ammonium carbonate* are given at 7@9c. per lb. according to seller, with lower prices named by importers. It is stated that the lower figure may be shaded on business of a large nature. Importers of *barium chloride* offer prime white crystals at \$48 per ton on the spot and \$46 per ton for arrival. Prices on *barium peroxide* around 24c. per lb. are named for the 86@90 per cent by makers. Offers as low as 17c. per lb. are heard in the spot market, but this material is off grade and it is doubtful if better than 20c. per lb. could be done for good grades.

Small lots of spot *bichromate of soda* are moving at 8c. per lb. and the market appears quite steady on this basis. It is admitted that a few odd lots might be purchased at a slight concession, but dealers are inclined to hold steady at former levels and in some directions higher prices are

named. Transactions are chiefly of a jobbing character, involving only small tonnages. Solid *caustic soda* is higher than noted a week ago, and \$3.90 per 100 lb. was the general quotation for standard brand goods ex-store. Moderate trading was reported at this figure and the tone of the market looked much steadier. Producers are holding contract prices at 3¼c. per lb. f.o.b. works, basis 60 per cent, in carload quantities. Manufacturers of *hyposulphite of soda* are accepting business at slightly lower figures, and sales are reported on a basis of \$3.40 per 100 lb. in car lots and 3¼c. per lb. in less than carload quantities. The absence of important business in *nitrite of soda* has left the market in a dormant condition. The general quotation is 7@7¼c. per lb. according to seller and quantity. A slight reduction might be granted on a firm order for a round lot. Spot sales of *prussiate of soda* are reported at 11¼@12c. per lb. and the market was quoted firm at the inside figure. In some quarters it was stated that inquiries were a little freer, although it was admitted that the call was chiefly for small lots. Light *soda ash* on spot is holding quite steady with sales reported at \$2.15@\$2.20 per 100 lb. in single bags. Barrels are selling at \$2.40@\$2.50 per 100 lb. ex-store. The inquiry for small quantities in barrels is reported fairly active. Producers continue to name \$1.60 for single bags and \$1.95 for barrels, basis 48 per cent, f.o.b. works. Special prices are being named on contracts to the consuming trade, the price depending upon the quantity involved. Imported ash is offered at \$1.60 per 100 lb., prompt shipment from abroad. Consumers of *bleaching powder* are showing an interest, and sales f.o.b. works are reported from 2@2¼c. per lb. in large drums. A few small drum sales occasionally go through at 2¼@2½c. per lb. f.o.b. works. Spot material is quite scarce, with prices about ¼c. above those named at the works for prime fresh material. Dealers of *formaldehyde* are quoting spot material in barrels at 13c. per lb. Some of the larger sellers have accepted less than this figure and state that they have placed business down to 12c. per lb. The low price, however, is confined to large lot quantities. Spot *oxalic acid* is quoted at 16c. per lb. and upward, depending upon the seller and quantity. It is stated that imported material is becoming scarce and that most of the business is on domestic stock. The extreme range of prices is 16@18c. per lb. Prices on white *sal ammoniac* vary considerably and the market at present is governed by the views of individual sellers. The range is from 6@7½c. per lb. The gray material is moving at 7@7½c. per lb., according to quantity, producers naming the inside price f.o.b. works. Importers of fused *sodium sulphide*, 60 per cent, are offering goods at 4½c. per lb., against a domestic price of 5@6c. per lb. Importers of *chlorate of potash* are offering lower at 7½@8c. per lb. Domestic prices are still held at 12@13c. per lb., although subject to shading. Very little interest has been noted from consumers of *caustic potash*, and prices are very soft, although quoted values remain unchanged. Quotations of 4¼@4½c. per lb. are heard from importers, but it is probable that shading of these figures could be done for firm business of a large nature. Domestic makers are still unable to compete.

COAL-TAR PRODUCTS

During the past week buying has been light and consumers show little disposition to change their hand-to-mouth methods. The decision of the tariff question is expected to improve feeling, although there is little reason to believe at present that any pronounced revival can come before some decision is reached. Interest, in the meantime, is centered around Washington and the ultimate fate of the licensing feature is anxiously awaited. There are some in the trade who are of the opinion that even the decision of this question will have little effect until general business is better. This is not the general belief, however, in chemical circles. In the absence of any market demand, prices are only secondary and it seems probable that any figures quoted can be materially shaded for firm business. Occasional orders are coming in, but the general tone is dull. Benzene still continues scarce and high in second hands where supplies are only to be had. Beta naphthol continues weak, with makers showing signs of further

weakness. *Paranitraniline* in resale hands is scarce, and makers are firm in their ideas. Producers of *benzene* are firm at 27@33c. per gal. Supplies are limited and export business is being turned down. Resale goods are hard to get, with some odd lots selling at 34@36c. per gal. Sales of *phenol* at prices ranging from 7@9c. per lb. have been made, but it is believed that the quality of these low-priced goods is not up to standard. Offers of prime goods at 9½c. per lb. have been heard. Better prices could undoubtedly be had on firm business, as there is a great amount of surplus stocks in practically every direction. Producers ask 15@16c. per lb. Prices on *H acid* are named at \$1.15@\$1.25 per lb., according to maker. A few small orders have come in, but few consumers are interested. The market on *aniline oil* continues dull, with makers willing to compete for business near the 20c. level. Resale lots are said to be available in moderate quantities as low as 18c. per lb. Makers are pretty well in line at 20c. per lb., although higher figures are quoted in some quarters. Some improvement has been noted in the demand from the rubber trade. Offers of low-priced *benzidine base* are very scarce and it seems probable that no first quality material can be had below \$1@\$1.10 per lb., quoted according to maker. Consumers are not showing much interest and it seems that even lower prices would not induce them to buy at present. Makers of *dimethylaniline* are quoting down to 45c. per lb., while others hold for prices up to 60@64c. per lb. The resale market is practically bare of supplies. The demand, in general, is rather slow. Makers' prices on *diphenylamine* rule at 65@70c. per lb. according to quantity. Business in this commodity is somewhat slow. Manufacturers of *paranitraniline* are holding their prices at 79@82c. per lb., merely to feel out prospective buyers. There is unquestionably a tendency to shade these figures rather than lose any passing business.

VEGETABLE OILS

Some importers of *chinawood oil* reported the spot situation as slightly easier, but with actual offerings scanty, the market was merely nominal where prices were concerned. Recent business in spot oil went through at 17c. per lb., but it was said that scattered lots could have been picked up at concessions. One operator thought that 12c. could be done. Early September arrivals were offered at 12½c. per lb., with buyers backward. September-October shipment from the Orient closed at 10¾@11c. per lb., c.i.f. New York. The market for *coconut oil* was less active, but prices for Manila oil on the Coast ruled firm. One sale was recently noted of 500 tons, sold on the bulk basis of 7½c. per lb., c.i.f. San Francisco. Scattered lots of tank cars were reported at 8½c. per lb., f.o.b. Coast, September-October shipment. Some holders on the Coast were asking 8½c. per lb. for prompt and nearby oil. Receipts of *olive oil* from Italy and Spain continue on a liberal scale and the market has shown no signs of improvement. Prices for edible oil were unsettled, ranging from \$1.80@\$2.20 per gal. Denatured oil closed nominally at \$1.10 per gal. Both soapmakers and tin plate mills have been showing more buying interest in *palm oils* and importers report that a good volume of business has been placed during the past week. *Lagos oil* is offered sparingly on spot in small lots as high as 7½c. per lb. On shipment goods, 7c. was asked. *Niger oil* closed at 5¾c. per lb. to arrive, with sales noted around this level. There was a quiet but steady market for domestic crude *peanut oil*. At the close holders were asking 7½c. per lb., buyers' tanks, f.o.b. mills for the prime quality.

The St. Louis Market

ST. LOUIS, Aug. 19, 1921.

There is evidence of a broadening of business in many localities, with more frequent spot orders, increased quantities and wider range of material which has stimulated the market quite a bit. Furthermore it is apparent that more confidence and optimism exist for the future. It is the opinion of most of the factors that the disturbing element which existed has been practically eliminated, which they hold as indicative of sounder and more stable business for the coming season. The general trend of the

market continues to be downward and many commodities undoubtedly have reached a minimum.

ALKALIS

Sal soda is very dull. *Soda ash* remains at manufacturers' schedule with slight increase in demand and movement. *Sodium bicarbonate* demand is quiet with prices from \$2.60 to \$2.75 per 100 lb. in less than carlots. *Caustic soda* continues to enjoy good demand. Contract buyers continue to consume their allotments and the price has stiffened to \$4 per 100 lb., basis 73-75 per cent solid, f.o.b. point of production.

CHEMICALS, DRUGS AND PHARMACEUTICALS

Acetanilid and *acetphenetidin* are not moving, due to the fact that these are unseasonable products. *Bismuth subnitrate* continues to move in large volume and manufacturers are in position to keep abreast with the demand. *Caffeine alkaloid* shows no exceptional activity and makers recently reduced their price. *Carbon bisulphide* is still among the active articles, with a demand for substantial quantities. Business in *chloral hydrate* is not very brisk and shading in prices has been heard of but without confirmation. *Cream of tartar* commands a fair demand. Manufacturers report a good volume of business on *cumarin*. *Glycerine* has declined no further and was quoted for spot and contract at 14½c. per lb. Little effort was being made by the producers to book contracts, as they consider the present price too low. *Soda glycerophosphate* has recently been reduced. *Hydrogen peroxide* continues to move steadily, but is still below past sales. *Iodides*, particularly potash, have shown an encouraging increase during the past two weeks. Now is the time to prepare for the winter season and wholesalers and consumers should not overlook their stocks on *salicylates*, *guaiacols*, *creosote* and *acetyl-salicylic*, as these articles will certainly be in demand with the first cold period. *Sulphur* continues in routine demand with advance in price of \$2.10 per 100 lb. for commercial in bags. *Zinc oxides* remain the same in price and demand is much below routine. *Zinc sulphate* is being offered at 3½c. per lb., f.o.b. St. Louis, with few inquiries.

ACIDS

Producers report a very appreciable increase in inquiry and demand for heavy acids, especially *sulphuric acid*, which is now moving in good volumes, and the manufacturers are very optimistic regarding the future. In some localities the demand for *citric acid* has improved, but the general demand is still below normal. *Acid pyrogalllic* continues to increase. *Tartaric acid* is favorable with a routine business.

VEGETABLE OILS

Linseed oil declined to 75c. basis raw in barrels from warehouse and has recently advanced again and holds very firm at 78c., with further advances expected. *Castor oil* continues in good demand, with price firm at 11½c. per lb. for No. 1 U.S.P. in returnable drums. *Turpentine* has advanced from its position of two weeks ago, and today is quoted at 60½c. in 5-bbl. lots. The demand is also better.

PAINT MATERIALS

Lithopone remains same in price with slight increase in demand. Many inquiries are being received on *dry earth colors* for the purpose of revising costs for the expected fall demand.

The Iron and Steel Market

PITTSBURGH, Aug. 19, 1921.

It requires very close analysis to show any change in the steel market situation in the week under review. There is a slight increase in demand upon the mills, in the aggregate, but the increase is probably smaller than in recent weeks, the trend toward heavier demand having begun about the middle of July. The character of demand is unchanged, orders being widely distributed geographically and by classes of buyers, while orders are, as formerly, chiefly for single carloads.

Steel prices likewise show little if any change. The regular or openly quoted prices are unchanged, there having indeed been no material change since the beginning of the

month. As for some time past, concessions can be obtained from these prices in the case of particularly desirable orders, whether in point of tonnage or of specifications. It is a question whether the concessions average more or less than a fortnight ago, but a change either way would not prove the market to be either better or worse. A larger concession might be quoted because a larger order was offered, or concessions might be less because less desirable business is going.

Much of the comment on the steel market is along the line that there is no forward buying, hence the market is still in very poor shape. This scarcely seems like a practical view. Steel mill operations dropped to below 20 per cent of capacity at the middle of July, and it ought not to be difficult to arrive at the conclusion that the mills needed prompt buying first. It is true that forward buying is essential in order that prices may be advanced, but the first objective of the steel mills necessarily is more business.

Steel mill operations have probably attained an average close to 25 per cent of capacity, against an average of about 21 per cent in July and a low point of less than 20 per cent at the middle of that month. This is on the basis of ingot production. Shipments of finished steel products have increased somewhat more, as there has been drawing upon the small remaining stocks of finished steel at mills, as well as a little rolling of semi-finished steel that had accumulated.

On the whole, the proportion of demand that comes from jobbers as compared with the demand from manufacturing consumers seems to be above the normal. This would tend to confirm the general analysis of the situation given in previous reports, that demand has suffered on account of the existence of stocks of steel and of manufactured goods, which have to be liquidated. The jobbing demand, which is for material to be distributed at once to small users, would naturally not be affected so much by stocks. It is noted that jobbers in the South, catering to agricultural trade, are particularly active.

There is heavy demand for galvanized sheets for making and repairing box car roofs, against the requirements of the fall movement of agricultural products. The automobile trade is somewhat more active than a month or two ago and while production of automobiles is below the best rate in the late spring the demand for steel is greater because at that time stocks of steel were being used. There is only a little demand from the oil fields, nothing at all comparable to a normal demand.

PRICES

As to openly quoted prices for steel products, against inquiries for carloads to 100 tons, prices of the leading products are unchanged since about the first of the month, except that blue annealed sheets are now commonly quoted at 2.25c. for orders at all attractive, against 2.40c. quoted a week ago. Concessions from regular prices, when named on attractive inquiries, are generally \$1 or \$2 a ton, occasionally reaching \$3 a ton, and this applies to most commodities except wire products and standard steel pipe, concessions on which are relatively small.

Pig iron has begun to show signs of an advancing tendency, this being a natural reaction, since in many cases prices done in the open market had passed below the cost of replacement, and were due to a desire to liquidate stocks. While buying has appeared to be very light right along, it appears that there really has been considerable liquidation. Some Chicago furnaces had sold foundry iron at \$18 furnace, while quotations are now advanced to \$20. Whether there will be any buying at the new price remains to be seen. In the valley market there is the interesting development that many if not all the producers have marked up basic iron from \$18 to \$20. Even in the latter part of last week there were sales on the \$18 basis. The valley market remains quotable at \$20 for bessemer, \$18 for basic and \$19.50 for foundry, f.o.b. furnace, on the basis that the market is quotable at last sales made.

Connellsville furnace coke remains at \$3 as the common asking price, with concessions frequently possible of about 10c. on standard coke. Standard foundry coke remains at \$4@4.50.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

EL DORADO—The Arkansas Royalty Co., Little Rock, is planning for the construction of a new gasoline-refining plant at El Dorado, with initial capacity of about 5,000 gal. per day. Lee Miles is president.

California

PASADENA—The Pasadena Military Academy, Oak Knoll, has preliminary plans under way for the installation of a complete chemical and scientific laboratory at the institution.

MONTEREY—R. F. Angulo, Santa Barbara, Cal., manufacturer of ceramic tile products, is planning for the construction of a new plant in the vicinity of Monterey. Clay properties suitable for tile production have been acquired in this section.

LOS ANGELES—The California Gypsum Corp., 731 Pacific Finance Bldg., is planning for the erection of a new plant at Coyote Wells, Imperial County, for the manufacture of gypsum products. The plant is estimated to cost about \$650,000 with machinery, and will consist of a crushing plant, with mining machinery, to cost approximately \$100,000; plaster mill and auxiliary buildings costing \$350,000; and railroad line construction to make connection with the San Diego & Arizona R.R., estimated to cost \$200,000. R. W. Waterman is construction engineer.

Connecticut

STAMFORD—The Yale & Towne Mfg. Co., manufacturer of locks, builders' hardware, etc., has commenced the installation of a new annealing department at its plant, to be used for truck bearing production and other construction. The plant, comprising an arched tunnel, will be electrically operated. A new 2-ton electric furnace has been installed for the manufacture of steel and malleable iron castings, heretofore purchased from outside sources. It is proposed to operate the furnace under 4 heats a day, or with total output of eight tons of material for the period.

Florida

TAMPA—The Peninsula Tire & Rubber Co. is perfecting plans for the erection of its new local plant for the manufacture of tires and other rubber products. The main building will be two-story, 100 x 300 ft., with two smaller structures, each about 60 x 60 ft. The plant will be equipped for an initial output of about 300 tires per day, and is estimated to cost approximately \$200,000. The company was incorporated recently with a capital of \$1,000,000. A. H. Van Auken is general manager.

Illinois

CHICAGO—The G. A. Ball Bearing Co., 3051 West Lake St., manufacturer of steel ball bearings, will take bids at once for the erection of its proposed one-story addition, 208 x 230 ft., at West Lake St., and Albany Ave., estimated to cost about \$65,000. Burrett H. Stephens, 37 West Van Buren St., is architect.

Indiana

INDIANA HARBOR—The Inland Steel Co. has commenced surveys of its property in Portage Township, Porter County, where recent purchases totaling about 640 acres of land have been made. The site will be used for the construction of a new steel works. No announcement has been made as to when construction will be inaugurated.

JASPER—Louis Mehringer, receiver for the Jasper Tire & Rubber Co., has arranged for the sale of the company's property.

Kentucky

PADUCAH—The Ohio-Kentucky Fluorspar & Lead Corp., City National Bank Bldg., recently formed with a capital of

\$1,000,000, has leased the properties of the North American Fluorspar & Lead Corp., at Smithland, Ky., and plans extensive development of the site, aggregating about 1,000 acres. A plant will be established to develop a daily production of about 100 tons of lead and fluorspar. T. J. Clay is president and F. B. Moodle, vice-president and general manager.

Louisiana

BASTROP—The Bastrop Pulp & Paper Co. is planning to begin operations at its new local pulp and paper mill, now in course of erection, early in October, and work is being pushed for the completion of the plant. The mill will have an initial output of about 60 tons of pulp, dry weight every twenty-four hours, and will represent an investment in excess of \$600,000. The company is affiliated with the Kansas City Packing Box Co. and the Kansas City Fiber Box Co., both of Kansas City, Mo., with L. H. Fox heading all three organizations. The entire output of the new pulp and paper mill will be utilized at the Kansas City mills.

LEESVILLE—The Louisiana Oil Refining Co. and the Caddo-Central Oil & Refining Co. will rebuild the portions of their local plants, recently damaged by fire, with loss reported at \$22,000.

Massachusetts

LOWELL—The Wamesit Chemical Co. recently incorporated with a capital of \$100,000, has acquired the entire plant and business of the Avery Chemical Co., and operations in the future will be conducted by the new organization. George Stevens is president, and John H. Murphy, 8 Shattuck St., treasurer.

GARDNER—Otto W. Siebert, until recently connected with the Bay State Metal Wheel Co. and the Children's Vehicle Corp., both of East Templeton, Mass., has leased the Wright property on Main St., and a building in the vicinity on Logan St., for the establishment of a new plant for the manufacture of fiber vehicles for children, and other fiber specialties. The structures will be remodeled and improved, and machinery installed at an early date. It is proposed to have the new works ready for service during the fall. At a later date, within the coming year, it is planned to construct an entirely new plant in this section for the same character of production.

Maryland

BALTIMORE—The American Sugar Refining Co., 117 Wall St., New York, is arranging for the operation of its new sugar mill in the Locust Point district, Baltimore, early in the coming year. Construction work is being pushed and machinery will be installed as soon as the buildings are ready. The plant will represent an investment of about \$8,000,000 and give employment to more than 2,000 operatives.

Michigan

NILES—The Hercules Steel Post Co., is having plans prepared for a new local plant, to be one-story, 50 x 250 ft., and estimated to cost about \$25,000. Erection will be commenced at an early date. G. J. Pammel, secretary of the local Chamber of Commerce, is handling the details of the project.

Minnesota

DULUTH—The Minneapolis Steel Co., a subsidiary of the United States Steel Corp., has acquired a tract of land totalling about 330 acres in the vicinity of its plant in the Morgan Park section. The acquisition gives the company control of the waterfrontage along the St. Louis River, between New Duluth and the present works. It is said that the site will be used for additions to the steel plant, with cost estimated in excess of \$5,000,000.

Missouri

JOPLIN—The Nichols Wire & Sheet Metal Co. Tenth and Missouri Sts., has plans under way for the erection of a 1-story works building, 50 x 200 ft., at 513 East Fifth St.

Montana

BUTTE—The Anaconda Copper Mining Co. is said to be planning for the erection of a new wire insulating plant at Great Falls, to be used in connection with its copper wire and rod mill here.

Nevada

MINA—The Mina Mercury Co. has construction under way on two new retorts at its plant to increase the output to four flasks of quicksilver daily.

Newfoundland

ST. JOHN'S—The A. E. Rex Co. is considering the rebuilding of its pulp mill at Bishop's Falls, destroyed by fire, July 27, with heavy loss.

New York

BUFFALO—The Iroquois Natural Gas Co., Iroquois Bldg., has tentative plans under way for the construction of a new artificial gas plant, estimated to cost about \$4,000,000. The proposed plant will be operated in conjunction with the company's natural gas system. Application is now before the Public Service Commission for the acquisition of the local gas properties of W. J. Judge, Buffalo Gas Co., by the Iroquois company.

Ohio

TOLEDO—The Spitzer Paper Box Co., 3051 Monroe St., is taking bids for the construction of a 3-story addition, 30 x 50 ft., estimated to cost about \$50,000. George B. Rheinfrank, Gardner Bldg., is architect and engineer. Lyman Spitzer is president.

TOLEDO—The Libbey Glass Co. will increase its working force by about 400 operatives, effective at once. Former employees at the plant will comprise the majority of the greater working force.

CLEVELAND—The International Steel Tire Co., 15702 Waterloo Rd., is considering tentative plans for the erection of a new plant on Waterloo Rd. It is proposed to commence construction during the coming fall. W. P. Day is president and T. J. Lavan, company address, engineer.

SHELBY—The Shelby Sales Book Co., manufacturer of paper specialties, has awarded a contract to the D. Mohler Construction Co., West First St., Mansfield, O., for the erection of a 1- and 2-story addition to its plant. Construction will be commenced at once.

Oklahoma

LAWTON—A. L. Lund, Lawton, and associates are planning for the immediate establishment of a new paint manufacturing plant, with initial daily output of about 1,000 gal. of material.

Pennsylvania

BROWNSVILLE—The Brownsville Window Glass Co. is planning for the rebuilding of its plant, destroyed by fire Aug. 6, with loss estimated at about \$300,000, including machinery. W. S. Phillips is general manager.

Texas

MEXIA—O. H. Foster, Breckrenridge, Tex., and associates are organizing a new company to construct and operate an oil refinery at Mexia. A tract of about fifty acres of land has been secured in the northern section of the borough, and plans are under way for a refinery to cost about \$400,000.

TEXAS CITY—The Swiftsure Petroleum Co., Houston, Tex., is planning for the construction of a new topping plant at its works at Texas City, comprising the former plant of the Bennett Petroleum Co., recently acquired. Mills Bennett is president.

Virginia

RICHMOND—The Richmond Pressed Metal Works are planning for the rebuilding of the portion of their plant recently destroyed by fire.

West Virginia

WHEELING—The Bonita Art Glass Co., recently organized with a capital of \$100,000, has plans under way for the erection of a new local plant, consisting of two buildings, each about 60 x 80 ft. George E. House is president, and Otto Jaeger, secretary-treasurer and manager.

MORGANTOWN—The United States Window Glass Co. is arranging for a resumption of operations at its local plant, known as the Seneca Works, on Aug. 25. It is proposed to develop capacity output in about a month.

Capital Increases, etc.

THE SCOBEL-MILLER CHEMICAL Co., Rochester, N. Y., has filed notice of increase in capital from \$20,000 to \$60,000.

THE NATIONAL INDEPENDENT OIL Co., York, Pa., a Delaware corporation, has filed notice of increase in capital from \$200,000 to \$500,000.

THE COLUMBUS FOUNDRY Co., Columbus, Ind., has filed notice of increase in capital to \$25,000.

THE SOUTHERN ELECTRO STEEL Co., Lynchburg, Va., has increased its capital to \$100,000. Joseph Keyser is president.

THE IMPERIAL WALL PAPER Co., Queensbury, N. Y., manufacturer of paper products, has increased its capital from \$750,000 to \$900,000.

THE KEINER-WILLIAMS STAMPING Co., Vine St., Brooklyn, N. Y., manufacturer of stamped metal products, has filed notice of increase in capital from \$300,000 to \$500,000.

THE GIBSON-ZAHNISHER OIL CORP., a Delaware corporation, has filed notice of organization to operate in New York, with capital of \$300,000, for the manufacture of oil products. J. F. James, 501 Fifth Ave., represents the company.

New Companies

THE RICHDALE OIL CORP., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture oil products. William G. Todd is president; and John F. Ryan, 18 Tremont St., treasurer.

THE INDEPENDENT PAPER MILLS, INC., Brooklyn, N. Y., has been incorporated with a capital of \$50,000 to manufacture paper products. The incorporators are P. W. Horwitt, L. Laveck and D. E. Latham, 280 Broadway, New York.

THE KANE CHEMICAL Co., Chicago, Ill., has been chartered under state laws to manufacture chemicals and chemical by-products. The incorporators are J. E. S. Teal, Louis Salinger and Charles E. Heckler, Room 1515, 111 West Monroe St.

THE REZNOIR CORP., Alden (Erie Co.), N. Y., has been incorporated with a capital of \$30,000, to manufacture molded and composition products. The incorporators are H. M. Dent, C. E. Leffel and F. J. Moore, Alden. The company is represented by A. W. Plumley, Mutual Life Bldg., Buffalo, N. Y.

THE PANHANDLE BRICK & TILE Co., Amarillo, Tex., has been incorporated with a capital of \$80,000 to manufacture brick, tile and other burned clay products. The incorporators are W. C. Pope, A. S. Stinnett and H. B. Boyle, Amarillo.

THE EXCEL ALL PUNCTURE-PROOF TUBE Co., Jersey City, N. J., has been incorporated with a capital of \$125,000 to manufacture rubber tubes for automobile tire use, and other rubber products. The incorporators are David A. Farrington, E. L. Williams and Frank G. Schafer, 673 Summit Ave.

THE PURE ALUMINUM Co. OF AMERICA, INC., New York, has been incorporated with a capital of \$100,000 to manufacture aluminum products. The incorporators are H. P. Armstrong, B. L. Shaw and E. E. Grabo. The company is represented by J. M. Coleman, 29 Broadway.

THE MATTSON WIRE & MFG. Co., Market and Lucas Sts., Joliet, Ill., has been chartered under state laws to manufacture wire and other steel products. The incorporators are Jesse A. Tune, C. N. and Elmer L. Crouch, F. A. Hill, 314 Barber Bldg., Joliet, represents the company.

THE INTERNATIONAL COTTON PROTECTING Co., Dallas, Tex., has been incorporated with a capital of \$25,000 to manufacture paste, compounds and other protective solutions for cotton service. The incorporators are S. Van deMark, and Edgar G. Macley, both of Houston, Tex.; and Charles J. Hinkley, Dallas.

H. J. STEIN & Co., INC., Boston, Mass., has been incorporated with a capital of \$25,000 to manufacture chemicals and affiliated products. Henry J. Stein, Holborn Street, Roxbury, Mass., is president and treasurer.

THE PETRONIO CHEMICAL Co., Newark, N. J., has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. The incorporators are Muzio Petroni and Frank A. Rizzolo, 510 Broad St.

THE D. & C. SPECIALTY Co., New York, N. Y., has been incorporated with a nominal

capital of \$5,000 to manufacture soaps, chemicals and affiliated products. The incorporators are D. T. Clavin, C. Curtis and M. Lieberman. The company is represented by M. E. Seiling, 358 Fifth Ave.

THE IROQUOIS MFG. Co. OF PENNSYLVANIA, Scranton, Pa., has been incorporated with a capital of \$10,000 to manufacture paints, varnishes, etc. W. E. Woehrman, 6408 Euclid Ave., Cleveland, O., is treasurer.

THE COCHRANE CHEMICAL INDUSTRIES, INC., Augusta, Me., has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. E. M. Leavitt is president and treasurer; and S. L. Fogg, director, both of Augusta.

THE CULBERSON COUNTY SULPHUR & DEVELOPMENT Co., Austin, Tex., has been incorporated with a capital of \$30,000 to manufacture sulphur products and operate properties of this and kindred character. The incorporators are J. Miles Hall, H. C. Morrow, Sr. and Jr., all of Austin.

THE GROVE Co., Philadelphia, Pa., has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. M. A. Sherman, 1220 Herbert St., Frankford, Philadelphia, is treasurer.

THE VICTOR LENS MFG. Co., Camden, N. J., has been incorporated with a capital of \$125,000 to manufacture lenses and other precision glass products. The incorporators are Clifford A. Baldwin, George D. Rothermel and Albert E. Burling, 520 Market St.

THE MARL LIME & FERTILIZER Co., 1030 Citizens' National Bank Bldg., Los Angeles, Cal., has filed notice of organization to manufacture fertilizer products. A. J. and L. E. Robinson head the company.

THE RYAN OIL Co., Spencer, W. Va., has been incorporated with a capital of \$50,000 to manufacture refined oil products. The incorporators are Thomas P. Ryan, Spencer; Charles E. and William E. Hogg, Point Pleasant, W. Va.

THE LUCINDA REFINING Co., Lucinda, Pa., has been incorporated with a capital of \$200,000 to manufacture refined oil products. J. F. Eisworth, Lucinda, is treasurer.

THE NEW ERA CONCRETE TILE Co., Camden, N. J., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture tile, blocks and other molded products. The incorporators are Charles A. and M. M. Smith, and George C. Rogers. The company is represented by David R. Rose, 522 Market St.

THE PENN-OLEAN Co., Olean, N. Y., has been incorporated with a capital of \$50,000 to manufacture refined oil products. The incorporators are H. C. and M. G. Fleming, and G. Forbes. The company is represented by A. J. Hastings, Olean.

THE CAMARILLO-DOME OIL Co., Ocean Park, Santa Monica, Cal., has been incorporated with a capital of \$50,000 to manufacture petroleum products. The incorporators are S. H. Bailey, George L. Adams and R. R. Robbin, Santa Monica. The company is represented by Tanner, Odell & Taft, attorneys, Santa Monica.

THE CENTRAL MAINE BRICK & STONE CORP., Fairfield, Me., has been incorporated with a capital of \$50,000 to manufacture brick and other burned clay products. Desire Baker is president; and William Seltzer, treasurer, both of Fairfield.

THE CHOCTAW COTTON OIL Co., New York, N. Y., has been incorporated under Delaware laws with capital of \$1,500,000 to manufacture cottonseed oil and other vegetable oils. The company is represented by A. W. Britton, 65 Cedar St.

THE NORTH METAL & CHEMICAL Co., York, Pa., has been incorporated with a capital of \$50,000 to manufacture chemicals and other products. H. B. North, York, is treasurer.

F. SCHOFIELD, INC., New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture petroleum products. The incorporators are F. Schofield, G. Reda and H. S. Leman. The company is represented by H. N. Wessel, 45 Cedar St.

THE INTERBOROUGH OIL Co., New York, N. Y., has been incorporated with a capital of \$25,000 to manufacture refined oil products. The incorporators are H. L. Schwartz, L. M. and M. Block. The company is represented by S. Brandt, 347 Fifth Ave.

THE RED RIVER OIL SHALE Co., Clay City, Ky., has been incorporated with a capital of \$250,000 to construct and operate a new oil-distillation plant in this section. J. W. Lee, Clay City, is president.

THE CO-OPERATIVE PAINT Co., 1315 Dalsey Ave., Long Beach, Cal., has filed notice of organization to manufacture paints, varnishes, etc. The company is headed by E. A. Smith, W. H. McLean and George H. Evans, all of Long Beach.

Industrial Notes

THE ANTI-HYDRO WATERPROOFING Co., New York, has developed an applied hardener or flush-on, known as Armortop, for use on old floors or floors that are laid truly monolithic. Armortop is a liquid chemical compound that is diluted with equal parts of water and is applied with a brush.

E. S. CROSBY, sales and advertising manager for the United States & Cuban Allied Works Engineering Corp., has resigned to become manager of the Eastern district of the Celite Products Co., 11 Broadway, New York City.

THE BARRETT Co. announces that since Aug. 1 its offices have been in its new building, 40 Rector St., New York City.

THE GEORGE J. HAGAN Co., Pittsburgh, Pa., has just completed the erection of a modern steel factory building adjacent to its foundry at Orrville, Ohio. This building is to be used for construction and development work on all types of furnaces and furnace equipments.

THE AMERICAN BOSCH MAGNETO CORP., Springfield, Mass., announces that Roy Davey, who has been manager of the Detroit branch, is now acting as manager of the manufacturers' trade department.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN PEAT SOCIETY will hold its fifteenth annual convention at the Hotel Commodore, New York City, Sept. 7, 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del., Oct. 18 to 20.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Number 9

The Cover Of This Number

MANY minds have collaborated in the production of this number of CHEMICAL & METALLURGICAL ENGINEERING. Author, manufacturer, editor, printer, artist—each has contributed out of the abundance of his knowledge and resources to produce for the reader a work of exceptional utility. It is altogether fitting, therefore, that the cover should foreshadow the excellence of the contents. The reader will at once be struck with the keynote which Mr. HOOVER has contributed specially for this occasion. With clear vision he sees the loss to the human race “in goods and services” due to waste and inefficiency in our industrial processes; and though he addresses a profession characterized by inventive genius that has been responsible for much of the marvelous progress of our time, he nevertheless asserts that greater good will result from the elimination of waste in industry than from great inventions.

Typical of the improvements in technology that have increased efficiency and reduced waste are the illustrations of the methods of making nitric acid in AGRICOLA's time and today. The illustration of the crude firebox with its retorts and condensers, reproduced from the Hoover translation of AGRICOLA's *De Re Metallica*, is in sharp contrast to the modern plant shown in part in the adjoining picture.

For the border design the artist has appropriately adapted a decoration from old German pottery of the time when AGRICOLA flourished.

Elimination of Waste in Industry

WASTE and inefficiency are the twin evils that today threaten American industry from within. They are dangerous characteristics because of their insidious nature, and they are reprehensible because generally they are remediable. Blameworthy at all times, they are especially so when avoidable waste and increased efficiency offer the quickest and surest opportunities for reducing losses or increasing profits. The elimination of waste is something that is within our control if we but give thought to it, in contradistinction to those fundamental economic forces that work inexorably and against which it is useless for us to strive.

In casting about for an editorial theme for this annual number of CHEMICAL & METALLURGICAL ENGINEERING, it seemed both wise and appropriate to make a contribution to the elimination of industrial waste. The whole world is recovering from an orgy of economic waste followed by a revel in extravagance such as we have never seen. Heedless of warnings and forgetful of the lessons of other wars and periods of reconstruction, we have approached the very brink of industrial disaster. In some cases it was necessary to meet ruin face to face in order to recognize it. And much of this distress

occurred in the very presence of industrial wastes the removal of which would have alleviated conditions, if indeed it would not have remedied them. Mr. HOOVER was right when, through American Engineering Council, he directed a survey of industrial waste as the most important investigation engineers could undertake.

Our readers will find the theme treated editorially in a variety of phases. It is reflected throughout the advertising pages as well, because it lends itself to the message of progressive manufacturers. If waste should be at a minimum anywhere, it is in the technologic industries that are founded on science and engineering. And yet, as will be shown later, there are vast opportunities for improvement even in those that are best regulated.

The contents of this number will fall naturally into two classes—a series of major articles on topics of broad interest and application, and a collection of brief surveys of the outstanding causes of waste and inefficiency in more than a score of industries. The major symposium opens with a study of human waste—that intangible charge against industry which is gradually being reduced to definite terms. Human effort is the foundation of industry, and accordingly the problems of health, food, housing, sanitation and recreation become the problems of industry; and the factors of contentment, loyalty and confidence assume a hitherto unrecognized degree of importance. Dr. MOCK finds that we have been as prodigal of human life and limb as of natural resources, and his solution of the problem is found in co-operation between engineers and physicians. Dean KIMBALL of Cornell contributes a thoughtful article on waste due to poor engineering and management, discussing the waste of materials and labor and the elusive waste due to idle equipment. Lost time due to poor planning, and depreciation of material due to poor storage or unwise purchasing are direct charges against poor management.

It will be recalled that the report of American Engineering Council charged management with responsibility for 50 per cent of present industrial waste. In discussing in this number the educational waste in industry Dr. HOLLIS GODFREY boldly lays responsibility for this condition back upon our educational institutions, believing as he does that the waste due to management “never could exist had there been proper co-operation between colleges and industry in the past.” In his judgment “education is the salvation of industry,” and the college man, properly trained, is badly needed. The rôle of scientific research in waste elimination is ably presented by HARRISON E. HOWE, who shows the great need for fundamental research in pure science in order to lay the groundwork for industrial research. The fallacy of curtailing or abandoning research in times of industrial depression and the tremendous cost of this policy are strikingly elucidated.

Doubtless we shall have to talk about standardization of chemicals and trade specifications for some time before they are accomplished facts. Two phases of the waste due to lack of these things are ably presented in this number. WALLACE P. COHOE stresses the losses in raw materials and finished products which result from lack of careful standardization, and WELLINGTON GUSTIN lays bare the appalling waste in litigation arising from the same cause. Litigation seems to be an inevitable consequence of doing business, but it is the height of folly to invite it by failing to know in advance the basis on which business is being done. Without standardization and trade specifications, buyer and seller not only have no common ground on which to initiate business but they have no accepted authority to which they can turn in case of dispute. The consequence is a waste in litigation that is a considerable charge against industry.

Are you wasting time and production in your industry due to lack of personnel selection and training? If such a problem confronts you, you will find food for thought in the article by L. B. HOPKINS. Improper selection of personnel is responsible for the waste inherent in high labor turnover, and failure to recognize the value of training, transfer and promotion of deserving employees adds another unnecessary burden to industry. Of the same order of magnitude is the waste due to lack of efficient cost-accounting methods, as set forth by ERNEST J. WESSEN. In this connection it is refreshing to read that in devising an efficient system of cost-finding "a knowledge of engineering practice is indispensable." Familiarity with bookkeeping and clerical methods will not suffice.

Building construction is likely to be more active in the near future than it has been for some years past, and accordingly we may give thought profitably to the elimination of construction wastes. Mr. BURPEE gives us a comprehensive analysis of the preventable wastes in this important industry, reducing to dollars and cents the cost of such items as abnormal risk, accidents, labor turnover, restriction of output and manner of letting contracts. Having built our factories after much planning and effort, we are apparently lax in protecting the structures against fire hazard. Our country has an annual fire waste amounting to about a quarter of a billion dollars, according to figures given in the article by NICHOLAS RICHARDSON. His review of fire hazards should prove specially valuable to the chemical industry. A related cause of waste and loss, and one that has not received the consideration it needs, is the location of industrial plants. Out of a large experience V. V. KELSEY discusses the influence which a proposed industry will have on the community, and the accessibility of raw materials, transportation, labor and power.

Closely related to other phases of the human problem in industry is that of accident prevention. Mr. DEBLOIS shows how attention to this factor can reduce waste and increase efficiency. The industrial accidents of the chemical industry should be carefully studied and analyzed as a basis for future precautionary measures. Some accidents are due to poor lighting, as WARD HARRISON points out in his article on the waste due to poor illumination. But there are other wastes chargeable to this neglected factor: time, materials and production are lost for want of enough light properly distributed throughout the factory.

The importance of machinery—automatic machinery

—in modern industry has been emphasized of late by the scarcity of labor and the tendency toward restriction of output. Mr. HIRES makes an excellent case for automatic machinery as a substitute for hand labor, showing that it is at once more efficient and economical as well as superior in its product. Closely related to mechanical operations are the production and use of power. There is a double interest in the subject for the chemical industries, because they usually want heat as well as power, and the question will arise whether to purchase from a central station or install an individual power plant. DAVID MOFFAT MYERS answers this question in his article on elimination of waste in power plants.

The problem of distributing and marketing the products of manufacturers is ably discussed by WILLIAM R. BASSET, who shows that faulty marketing represents a waste that is an unnecessary deduction from profit. It frequently happens that the manufacturer is weakest in his knowledge of marketing methods. He may know how to buy raw materials, and we may assume that he manufactures his product efficiently and economically, but there is ample evidence that he fails woefully at times to adopt the best selling policy. Mr. BASSET's article discusses the subject from the point of view of the manufacturer.

The economic waste and nuisance inherent in the smoke, fume and gas discharged from industrial plants is a charge against industry that has been reiterated by investigators until it is pretty well understood by even the man on the street. A great deal is constantly being done to eliminate this waste, but a vast amount remains to be accomplished. For this reason Mr. LANDOLT's article is a welcome contribution to the symposium. His analysis of methods for reducing this economic waste will be helpful to many industries.

The relation of the patent situation to industrial waste may not be apparent at first glance, but when one stops to think of the needless delays, the interferences and the litigation which industry incurs due to a poorly manned Patent Office, no excuse need be made for including Mr. PRINDLE's forceful article in our treatment of this theme.

The series of short articles featuring the outstanding causes of waste and inefficiency in the industries will have a fascination for the reader because of their frankness, if for no other quality. We regard them, however, as valuable contributions on the part of men who are fully cognizant of technical and economic conditions internal to their respective industries. Some of the contributions are anonymous or offered under *noms de plume* for the reason that the authors felt they could thus speak more frankly. The value of their criticism, however, is not diminished, but rather enhanced, by failure to disclose their identity. On the whole we regard the symposium as a notable contribution of its kind.

The contents of this number will not be digested at one sitting, nor in a week or a month. The contributors are specialists and authorities, and have written out of a large experience. The magazine thus acquires a reference value out of the ordinary. Nor does this apply to the text pages alone; equally careful attention has been given to the preparation of the advertisements so that they form a very practical guide to the industry. The entire number will be worthy of preservation intact regardless of the reader's practice with respect to binding volumes.

Chemical Exposition for 1921 To Excel Its Predecessors

IT has been characteristic of the National Exposition of Chemical Industries that each annual exhibit surpassed the preceding one, both as to the number of exhibitors and amount of floor space covered. To this general rule the 1921 show will be no exception. The space occupied by exhibits will be considerably larger than in 1920 and the number of exhibitors will exceed those of a year ago by a small number. Various interpretations might be put on this record, but in view of prevailing industrial conditions we think it is a tribute to the stability of American chemical industries and to the inherent optimism of their executives. A year ago, in the face of impending business depression, exhibitors gladly committed themselves to participation in this year's exposition. There have been some additions to and some subtractions from the list since that time, but on the whole, preparation for this year's show has been carried out in the face of obstacles that would daunt a less courageous industry.

Many conditions this year will contribute to make the exposition more satisfactory to the visitor than in past years. In the first place, the use of the Eighth Coast Artillery Armory will make it possible to present the entire exposition on one floor. This is not only a great physical advantage, but it will have a tremendous psychological value in enabling the visitor to get a better conception of the magnitude of the show and the industry it represents. For the first time appropriate provision will be made for the technical sessions and display of industrial motion pictures. Hitherto speakers and audience at these sessions have been disturbed by the noise of moving machinery and the crowds, but this year they can enjoy the programs in a room well apart from the main exhibition floor. The technical sessions are growing in favor and improving in value and are coming to be recognized as an important feature of the exposition. This year there will be a number of interesting symposia on industrial subjects and some of the papers will be preprinted. Taken all together, the exposition this year will excel its predecessors and will be far more satisfactory from the point of view of the visitor.

Five Years of Legislative Waste

WASTE in government is as old as government itself and many methods have been proposed for its elimination. The investigations of congressional committees, the reorganization schemes of the Bureau of Efficiency and the Director of the Budget, the work of the joint commission on reclassification—all are steps in this direction which may be expected to accomplish many worth-while savings. As long, however, as the lion's share of our appropriations continues to be spent for the upkeep of the Government's fixed establishments of Army and Navy, the economies effected by these agencies must necessarily be limited.

There is a source of waste in government which we hear less about but which cannot have escaped the attention of those who have followed the efforts to obtain protective legislation for the dye industry. The first genuine attempt on the part of the chemists of the country to obtain recognition for this important industry was in 1916 and the history of what has transpired since that time is a record of disappointing delays and

discouraging wastes of time and effort. Progress has been extremely slow and the occasional successes accomplished have been only temporary. For five years the industry has had to keep up a continuous battle. It has been necessary to tell its story many times and in many places. Its case has been argued before the Ways and Means Committee on at least four separate occasions and each time the case has been retried before the Senate Finance Committee. Many volumes of testimony have been recorded and printed by each committee notwithstanding the fact that few if any new arguments were advanced at the subsequent hearings.

For the benefit of those who have not followed the details of these legislative activities, let us review them briefly. The measure previously referred to was passed by Congress on September 8, 1916. It had been sponsored by a committee of the American Chemical Society and in its final form it provided slightly increased duties on dyes and intermediates for a period of five years. It was soon evident, however, that the new law was unsatisfactory in many ways and in December, 1918, the Tariff Commission officially called attention to the urgent need for its revision. In May, 1919, President WILSON in his annual message to Congress declared that "special consideration should be given to the manufacture of dyestuffs and related chemicals." A few days later the original Longworth bill was introduced and was referred to the Ways and Means Committee and extended hearings were held. At that time Army and Navy representatives testified to the importance of the industry from the standpoint of national preparedness. Shortly afterward a second bill was reported and referred to the committee for hearings. Finally, in September, 1919, the Longworth dye-licensing bill was passed by the House and, following the usual procedure, was sent to the Senate Finance Committee, which devoted several months to hearings on the subject. In the meantime the President's message to the Sixty-sixth Congress had repeated the earlier appeal for special dye legislation. In February, 1920, the modified selective embargo was reported to the Senate, but three months later it was defeated without a vote principally because of the persistent filibuster by Senators THOMAS and MOSES. Early in the present year the Ways and Means Committee held hearings on the general tariff revision and on June 29 reported the Fordney tariff. Before this measure was passed, on July 21, it will be recalled, the House eliminated the dye embargo, due largely to Congressman FREAR's insistence that a monopoly was being fostered. And now the Senate Finance Committee has just concluded another series of open hearings and, although the chemists have again made a strong appeal for the industry, the embargo question, still unsettled, has been referred to a joint sub-committee.

Such is the story of the dye bill—a measure which has been recognized as essential to the national defense, a non-political question supported by free trader and protectionist alike. Five years has elapsed and nothing permanent has been accomplished. Hearings have followed hearings, licenses and embargoes have been discussed and discarded, wartime control of imports has been extended and re-extended, and we now find ourselves just about where we started. It is obvious that our law-making processes are truly wasteful.

After such a condemnation of our legislative system, we should like to suggest a practical remedy. We hesitate, however, to approve the theoretical solution which

is so often proposed—viz.: Take the tariff out of politics; put it into the hands of a non-partisan tariff commission and give that body complete authority to deal with all tariff matters. If the tariff were more of an economic problem and less of a political factor, such a change might perhaps be accomplished. A compromise solution which appears to us to have some advantages over the present system would be to let the Tariff Commission take over all of the investigational work of the tariff and conduct all tariff hearings. The facts presented to Congress by this impartial body would then be used as the basis for our tariff legislation. The wasteful duplication of hearings and needless political debate would thus be eliminated and with this much accomplished we could look forward to more radical changes in our legislative processes.

The Man on The Firing Line

IN THE preparation of that part of this number which tells of the outstanding causes of waste and inefficiency in a score or more of industries we have naturally had a great deal of correspondence. Our effort has been to select the man available who is best equipped in each case and then to give him a free rein. It has seemed to us that this would be of greater value to our subscribers and more profitable to them than to wind ourselves up in rhetoric over the bigness, the grandeur—over what LAFCADIO HEARN once called “the ahness” of American chemical enterprise.

We wrote, among others, to a leading technologist who replied as follows:

Please excuse me from writing on the causes of waste and inefficiency in the — industry. A man on the firing line cannot comprehensively report a battle. He is too close and his vision is too limited. For that very reason I shall all the more appreciate the articles of those who have a broader vision or who can view the scene at a better perspective.

There would seem to be an anomaly in this, that the man on the job every day should fail to see that which is obvious to the stranger or the more casual observer. But we appreciate his point of view. It is not alone with distant forests that we cannot see the trees for the woods. We suffer a similar inhibition among familiar things that are right before our eyes. When a thing is settled, a problem solved and things are working smoothly, we naturally close our minds to further worry over the subject and address our attention to those things which we believe need it. The single-track mind is the usual mind, and we know well that our best method is to do one thing at a time and to strive to do it well. Then it is likely to happen that certain features which have had attention and have been adjusted in times past suffer from neglect because in the march of progress they have been overlooked. That which two years ago seemed excellent is not good enough for today. And the man responsible does not realize it. There is not a person alive who is up to date in every respect.

It is therefore very profitable for men on the firing line to have their work looked over occasionally. A critical audit of a plant is as important as an audit of books. There is no establishment so well run as to be beyond criticism or incapable of improvement from it. Whoever thinks that he has achieved perfection or that his work is above criticism is, by that very token, a back number. He has lost his scientific spectacles if he thinks so.

Chemical Supremacy With English-Speaking People

A HEARTY welcome is extended to British and Canadian chemists representing the Society of Chemical Industry who expect to spend the next two weeks in the United States. This will afford an opportunity for exchange of views and opinions and for a more intimate knowledge of chemical and industrial conditions on the part of hosts and visitors. These international visits are better guarantees of peace and amity than are treaties concluded by statesmen and diplomats.

But there is a deeper significance in the conclave of British, Canadian and American chemists in New York next week than will appear in the mere fraternizing of men who are already more or less well known to each other by reputation or through correspondence. True, the British have crossed the water, which is in itself no mean undertaking in these piping times of peace and reconstruction. And Canada is putting her best chemical foot forward, as befits a hostess who would honor eminent guests that have journeyed far in the name of the Society of Chemical Industry. And finally, British and Canadians will converge upon New York to meet with the American Chemical Society and visit the Chemical Exposition. The bare incidents are noteworthy, but in our judgment they mark an epoch. This international meeting of chemists lays the foundation for the recognition of chemical supremacy in the English-speaking people.

We might almost speak of the restoration of chemical leadership to the Anglo-Saxon race, for the early history of the science abounds in names of English rather than of Gallic or Teutonic investigators. Curiously enough, the diligence and industry of the Teuton in applying the fundamental discoveries and developments of his neighbors earned for him the reputation of being the repository of all chemical knowledge. And he capitalized on this reputation through his literature and universities, until it required a great war to disillusion the rest of the world and awaken a sense of equality and independence in science, particularly chemistry.

Signs are not lacking that the old order changeth, one of which is the fact that no longer are we dependent on German chemical literature for knowledge of what is being done by, say, Russian or Japanese investigators. As DR. BENJAMIN T. BROOKS points out in private correspondence, an increasing proportion of research and investigation done in foreign countries is being published in English, whereas formerly the German language was the medium through which most of us acquainted ourselves with the work originally published in Russian, Scandinavian, Dutch or Italian. German has been the accepted language of international chemistry, much as French has served in international diplomacy. Our own *Chemical Abstracts*, however, now presents abstracts directly from Russian and Japanese publications, and doubtless the work will be extended to the point where former dependence on *Chemisches Centralblatt* will be a vanishing quantity.

This is but one of the factors contributing to English-speaking leadership in chemistry, which is a consummation that, in our judgment, will come in due course. The international gathering of chemists in New York should be another powerful impetus toward the same end, and we express the hope that these benign forces may continue to act until English merits the distinction of being the international language of chemistry.

OFFICERS AND SOME OF THE VISITORS AT THE MONTREAL MEETING, WEEK OF AUG. 29, 1921, OF THE SOCIETY OF CHEMICAL INDUSTRY (BRITISH) AND AT THE NEW YORK CITY JOINT MEETING, WEEK OF SEPT. 6, 1921, OF THE AMERICAN CHEMICAL SOCIETY AND OF THE SOCIETY OF CHEMICAL INDUSTRY

1—Sir William J. Pope, president of the Society of Chemical Industry.
 2—R. F. Ruttan of Montreal, president-elect of the Society of Chemical Industry.
 3—S. R. Church of New York City, member of the co-ordinate committee for the joint meeting at New York of the American Chemical Society and of the Society of Chemical Industry.
 4—J. P. Longstaff, Secretary of the Society of Chemical Industry.
 5—E. V. Evans, honorary treasurer of the Society of Chemical Industry.

6—F. W. Atack, Editor of Chemists' Year Book.
 7—R. H. Clayton of the Manchester Oxide Co.
 8—F. W. Gamble, of Allen & Hamburg, Ltd.
 9—C. S. Garland, chairman of Lighting Trades, Ltd.
 10—Captain C. J. Goodwin, honorary treasurer of the Chemical Industry Club of London.
 11—L. A. Jordan of the British Nylonite Co., Ltd.

12—J. D. McBain, professor of physical chemistry at the University of Bristol.
 13—J. MacWilliam, consulting metallurgist, of Sheffield.
 14—H. W. Matheson, vice-president of the Canadian Electric Products, Ltd.
 15—J. Reid of the Caldercruix Paper Mills, Airdrie, Scotland.
 16—Andrew Smith, managing director of Leech, Neal & Co., Ltd.
 17—T. H. Wardleworth, of Canada, member of the General Council of the Society of Chemical Industry.

Program of the Exposition

Symposia Prepared by the Management on Crushing, Grinding and Pulverizing, Evaporating and Drying, Paint and Varnish, Power Plant in the Chemical Industries, and American Dyes—
Motion Pictures of a Wide Variety of Industrial Operations

FOLLOWING is the program of the Seventh National Exposition of Chemical Industries, to be held at the Eighth Coast Artillery Armory, Kingsbridge Rd. and Jerome Av., New York City, Sept. 12 to 17. The program as given here is subject to changes and additions:

MONDAY, SEPT. 12

2 p.m. Exposition opens.

7 p.m. Motion pictures (in Auditorium).

1. "Iron Mining Operations" (4 reels), courtesy U.S.B.M.*
 - a. Stripping.
 - b. Exploration and stripping.
 - c. Underground mining.
 - d. Logging operations.
2. "The Story of Abrasives" (4 reels), courtesy the Carborundum Co. and U.S.B.M.
 - a. Creating power from water.
 - b. Within the power plant at Niagara.
 - c. In and about the City of Niagara Falls.
 - d. Power at work in the Carborundum Plant.
 - e. Making the crystal masses in the electric furnace
 - f. and making them into stones, grinding wheels, paper and cloth.
 - g. Unusual and usual uses for abrasives in fifty industries.

8 p.m. Opening addresses.

Dr. Charles H. Herty, opening address.

Hon. Irvine L. Lenroot, United States Senator.

General Amos A. Fries, Chief, Chemical Warfare Service.

TUESDAY, SEPT. 13

2:30 p.m. Crushing, grinding and pulverizing symposium.
Chairman, Harry J. Wolf.

- H. F. Kleinfeldt, Abbe Engineering Co., "Ball and Pebble Milling for Pulverizing and Mixing."
S. B. Kanowitz, Raymond Bros. Impact Pulverizer Co., "Grinding and Pulverizing With Air Separation."
L. H. Sturtevant, Sturtevant Mill Co., "Crushing, Storing and Pulverizing."
M. I. Dorfan, Allis-Chalmers Manufacturing Co., "Dust Collection as Applied to Grinding and Pulverizing Problems."

H. Schifflin, Allis-Chalmers Manufacturing Co., "The Development of Compound Grinding Mills."

G. W. Repetti, the Dorr Co., "Mechanical Handling of Finely Ground Wet Material."

Industrial Problems:

H. Austin, Ernest Scott & Co., "Solvent Extraction of Edible Fats and Oils."

R. H. McLain, General Electric Co., "Materials Handling in Industrial Plants."

W. H. Dickerson, Industrial Products Co., "Utilization of Industrial Waste; Its Economic Importance."

To be followed by motion pictures upon the subject of the handling of materials if time permits. See the first four titles upon the evening program.

7 p.m. Motion pictures.

1. "Transportation and Storage of Iron Ore" (1 reel), courtesy U.S.B.M.
2. "The Story of Asbestos" (4 reels), courtesy U.S.B.M.
3. "Dredging Anthracite Coal" (1 reel), courtesy U.S.B.M.

4. "Saving Wasted Millions Through Material Handling Equipment" (2 reels), courtesy Economy Engineering Co.

5. "The Story of Sulphur" (2 reels), courtesy Texas Gulf Sulphur Co.

6. "Mining and Extraction of Radium From Carnotite Ore" (2 reels), courtesy U.S.B.M.

7. "DuPont Dyes," showing their manufacture (2 reels), courtesy du Pont de Nemours & Co.

8. "Making Soap" (1 reel), courtesy Baumer Films.

9. "Mine Explosion and Rescue" (1 reel), courtesy U.S.B.M.

8 p.m. Address, Hon. Fred S. Purnell, Representative from Indiana.

WEDNESDAY, SEPT. 14

2:30 p.m. Evaporating and drying symposium.
Chairman, Wallace Savage.

E. G. Rippel, Buffalo Foundry & Machine Co.

A. E. Stacy, Jr., Carrier Engineering Corporation, "The Relation of Atmospheric Conditions to Chemical Processes."

H. S. Landell, Proctor & Schwartz, "Drying and Dying Problems."

Max Donauer, Elyria Enameled Products Co., "Special Problems for Enameled Evaporators."

Arthur B. Stonex, Hunter Dry Kiln Co., "Drying With Moist Air."

A. W. Lissauer, W. L. Fleisher & Co., Inc., "Drying as an Air-Conditioning Problem."

J. D. Stein, Grinnell Co., Drier Division, "Atmospheric Drying by Means of Compartment, Tunnel and Continuous Belt Conveyor Driers With Some Practical Applications."

W. H. Dickerson, Industrial Waste Products Co., "Spray Drying."

H. Austin, Ernest Scott & So., "Evaporation."

Robert V. Cook, Chemical Equipment Co., "The Criss-Cross Evaporator: Why It Was Designed, What It Is, and What It Does."

J. S. Chen, J. P. Devine Co., "Vacuum as Applied to Industry."

7 p.m. Motion pictures.

1. "The Manufacture of Dry Sausage" (2 reels), courtesy Armour & Co.

2. "The Making of Oleomargarine" (1 reel), courtesy Armour & Co.

3. "The Electric Heart—The Dry Cell" (1 reel), courtesy Baumer Films.

4. "Canning Electricity—The Wet Cell" (1 reel), courtesy Baumer Films.

5. "The Manufacture of Pyrex Glassware" (3 reels), courtesy Corning Glass Co.

6. "The Manufacture of Portland Cement" (2 reels), courtesy U.S.B.M.

7. "The Manufacture of Dynamite" (1 reel), courtesy U.S.B.M.

8. "Exterminate the Mosquito" (1 reel), courtesy U.S.B.M.

THURSDAY, SEPT. 15, PAINT AND VARNISH DAY

2 p.m. Paint and Varnish Symposium.

Chairman, R. S. Perry, Perry & Webster, Inc., "Paint and Varnish Waste Control."

H. A. Gardner, Institute of Paint and Varnish Research, "Reflection Factors on Industrial Paints."

*NOTE: "U.S.B.M." on this program refers to United States Bureau of Mines.

SATURDAY, SEPT 17

L. P. Nemzek, du Pont de Nemours & Co., "Laboratory Control."

Maximilian Toch, Toch Bros., "Rust: Its Cause and Prevention."

Frank G. Breyer, New Jersey Zinc Co., "Physical Testing of Paints and Paint Materials."

F. P. Ingalls, John W. Masury & Co., "The Ideal Paint and Varnish Specifications."

D. A. Kohr, Lowe Bros. Co., "Limitations of Standardization of Paint and Varnish Manufacture."

7 p.m. Save the surface; paint and varnish speakers and motion pictures.

Ernest T. Trigg, chairman, "Save the Surface" Committee, Paint Manufacturers Association of the U. S., "Save the Surface and You Save All With Paint and Varnish."

G. P. Heckel, secretary, Paint Manufacturers Association of the U. S., "What Is Paint?"

To be followed by motion pictures.

1. "Making White Lead" (2 reels), courtesy Bureau of Commercial Economics and National Lead Co.
2. "Making of Varnish" (1 reel), courtesy Bureau of Commercial Economics and Murphy Varnish Co.
3. "Making of Paint and Varnish" (2 reels), courtesy Bureau of Commercial Economics and Sherwin-Williams Co.
4. "Making of Paint" (1 reel), courtesy Bureau of Commercial Economics and Lowe Bros.
5. "Making of Paint" (1 reel), courtesy Bureau of Commercial Economics and Mathews & Co.
6. "Making of Varnish" (1 reel), courtesy Bureau of Commercial Economics and Taylor, Tregent & Co.
7. "The Manufacture of Pyrex Glassware" (3 reels), courtesy Corning Glass Co.
8. "The Manufacture of Portland Cement" (2 reels), courtesy U.S.B.M.

FRIDAY, SEPT. 16

2:30 p.m. The Power Plant in the Chemical Industries Symposium.

Chairman, R. C. Beadle, Editor, *Combustion*.

R. M. Gordon, the Solvay Process Co., "Modern Boiler House Arrangement and Equipment" (illustrated).

John Primrose, Power Specialty Co., "Suggestions for Reducing Heat Losses in Chemical Plants."

E. C. Bashore, Rice & Bashore, "Boiler Feed Water Treatment and Treatment Control."

A. R. Stevenson, Jr., General Electric Co., "Compressed Air Installations in Industrial Plants."

D. B. Rushmore, J. A. Seede and E. Pragst, General Electric Co., "The Application of Electric Power in Chemical Industry."

F. G. Anderson, Morse Chain Co., "The Limitation of Silent Chain Drive."

D. S. Chamberlain, Distillation Industries, Inc., "A New Method for Coking Coal as Required for Industrial Fuel."

H. S. Savage, Combustion Engineering Co., "The Application of Pulverized Fuel."

Perry West, Anti-Corrosion Engineering Co., "The Prevention of Internal Corrosion in Pipes, Tanks and Other Iron and Steel Equipment."

7 p.m. Motion pictures.

1. "The Cost of Careless Firing" (2 reels), courtesy U.S.B.M.
2. "Getting the Most Out of Coal" (1 reel), courtesy U.S.B.M.
3. "Conserving Coal and Saving Heat Values by Insulating Steam Pipes and Boilers" (1 reel), courtesy Magnesia Association of America.
4. "Modern Byproduct Coking" (2 reels), courtesy the Koppers Co.
5. "The Story of Rock Drilling" (4 reels), courtesy Sullivan Machinery Co., and U.S.B.M.
6. "The Story of Armco Ingot Iron" (3 reels), courtesy American Rolling Mill Co.

2:30 p.m. American Dyes Symposium.

Chairman, Justin B. Weddell, Nat'l Aniline & Chem. Co.

"Early History of the Dye Industry."

"Marvels of Modern Chemistry."

"Practical Dyeing Problems."

"Color Harmony in Textiles."

"The Relation of Color to the Theater."

"World Disarmament and the Necessity of an Independent American Dye and Chemical Industry."

"Is There an American Dye Monopoly?"

7 p.m. Motion pictures (subject to change).

1. "Manufacture of Newsprint Paper" (5 reels), courtesy Spanish River Pulp & Paper Mills.

2. "Making du Pont Dyes" (2 reels), courtesy du Pont Co.

3. "Manufacture of Dynamite" (1 reel), courtesy U.S.B.M.

4. "Mining Magnetic Iron Ore" (2 reels), U.S.B.M.

EIGHTH COAST ARTILLERY ARMORY, KINGSBRIDGE ROAD AND JEROME AVENUE

Exhibitors at the Exhibition

A Brief Catalogue of the Products and Equipment to Be Exhibited at the Seventh National Exposition of Chemical Industries, Together With the Names of the Four Hundred Exhibitors and the Representatives in Charge of Their Exhibits

THE following scientific societies and publications have reserved booths for the Seventh National Exposition of Chemical Industries, where they will be glad to receive their friends.

AMERICAN CERAMIC SOCIETY.
 AMERICAN CHEMICAL SOCIETY.
 AMERICAN DYESTUFF REPORTER.
 AMERICAN PERFUMER AND ESSENTIAL OIL REVIEW.
 CANADIAN CHEMISTRY AND METALLURGY.
 CANADIAN MINING JOURNAL.
 CHEMICAL AGE.
 CANADIAN TEXTILE JOURNAL.
 CHEMICAL CATALOG.
 CHEMICAL COLOR AND OIL RECORD.
 CHEMICAL & METALLURGICAL ENGINEERING.
 COLOR TRADE JOURNAL.
 COMBUSTION.
 DRUG & CHEMICAL MARKETS.
 INDUSTRIAL AND EDUCATIONAL PRESS.
 IRON & STEEL OF CANADA.
 JOURNAL OF COMMERCE.
 JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY.
 MANUFACTURERS RECORD.
 OIL, PAINT AND DRUG REPORTER.
 PAPER MILL AND WOOD PULP NEWS.
 PULP & PAPER MAGAZINE OF CANADA.
 TEXTILE COLORIST.
 TEXTILE WORLD JOURNAL.
 TEXTILES.

The following list of exhibitors at the Exposition, together with a brief statement of their exhibits and the names of their representatives, will be of special value to those who expect to attend the Exposition. It is published well in advance in order to enable prospective visitors to conserve their time and to give their attention to those matters in which they are particularly interested. The list is practically complete. Where no description of exhibit is given, the information requested was not furnished or arrived too late for publication. No attempt has been made to give booth numbers or location in the Armory, because these will

be more easily obtained from the handbook and guide which will be distributed at the Exposition with the compliments of CHEMICAL & METALLURGICAL ENGINEERING.

ABBÉ, PAUL O., INC.—Pulverizing, grinding, crushing, and cutting machinery. Represented by Henry Sellman and John Buckley.

ABBÉ ENGINEERING Co.—Grinding and pulverizing machinery. Represented by H. F. Kleinfeldt and A. T. Beach, Jr.

ABERNETHY, JOHN F.—Lead burning, lead-lined tanks, acid containers made of lead, lead condensing coils, and various other chemical equipment of lead. Represented by John F. Abernethy and John J. Kiernan.

ACID-PROOF CLAY PRODUCTS Co.—Acid-proof chemical stoneware, including storage vessels, tower sections, faucets and piping in the various designs. Represented by N. E. Hansen and J. E. Cooper.

AINSWORTH, WILLIAM, & SONS.—Analytical balances with improved rider and weight carriers of the latest types, and an assay balance with reflection reading device sensitive to 1/1000 mg. Represented by W. H. Smith.

ALBANY CHEMICAL Co.—Solvent specialties and pharmaceutical products. Represented by K. E. Schoeneman and Edward S. Wright.

ALBERENE STONE Co.—Standard fixtures and equipment for research and educational laboratories, including a complete line of Alberene stone chemical hoods, sinks, drain boards, table tops, gutters and reagent shelves. Represented by A. Y. Meeker, F. E. Healy, W. K. Fields, E. C. Collins, Wesley Heins, R. G. Grothe, F. R. Nichols and N. N. Moneypenny, Jr.

ALBERGER CHEMICAL MACHINERY Co., INC.

ALLIS-CHALMERS MFG. Co., INC.—Operating models of dust collector, pulverator, motor-driven bronze pump, rubber-lined pump, direct current and induction motors, and air compressors. Represented by A. F. Rolf, W. E. Keine, M. I. Dorfan, T. Pilger, H. W. Dennison, A. J. Cooper, F. J. Geiger, O. H. Hentz, W. C. MacEwen, C. H. Paine, George Baiz, W. O. Taylor and W. H. Wolf.

AMERICAN CHEMICAL & MFG. Co.

AMERICAN COAL CHUTE Co.

AMERICAN CYANAMID Co.—Cyanamide, cyanide, liquid hydrocyanic acid, ferrocyanides, urea, dicyandiamide, am-

monia, ammonium phosphate, ammonium sulphate, ammonium nitrate, and nitric acid. Represented by E. J. Pranke, R. R. Stewart, F. S. Washburn, Jr., G. Thorn and A. E. Downes.

AMERICAN HARD RUBBER Co.—Chemical handling and conveyance equipment of hard rubber, including pumps, pipe fittings, tanks and utensils. Represented by A. M. Ackerman and D. W. Wilkins.

AMERICAN LAFRANCE FIRE ENGINE Co., INC.—Industrial safety devices, including the latest developments in breathing and eye protection for workers in chemical factories. Represented by James W. Knoblock, Arthur B. Crossman, R. C. Engels and J. E. Egan.

AMERICAN MANGANESE BRONZE Co.—The exhibit will show results of acid tests on various kinds of bronze castings and forgings used in the chemical trade, particularly those for centrifugals, valves and special castings made for sugar machinery. Represented by C. H. Spare, C. J. Bower and T. H. Addie.

AMERICAN METAL PRODUCTS Co.—A line of acid-resisting valves and fittings, rolled sheet and forged bronze, and bronze castings. Represented by C. J. Zaizer and A. S. Knowlton.

AMERICAN STEAM PUMP Co.

AMERICAN STEEL & WIRE Co.

AMERICAN WATER SOFTENER Co.—Model of pressure type filter and Decalso Zeolite type water softener; also a complete line of lime and soda water softeners. Represented by A. S. Garrett, W. T. Runcie, G. M. Graybill, J. B. Price and George F. Hodgkinson.

ANACONDA COPPER MINING Co.—An exhibit to illustrate the smelting and refining of copper, starting with ore and following through the various processes to the refined article. The various valuable byproducts, metals and chemicals obtained in the electrolytic refining of copper are shown. Other features of the exhibit will show the various applications of copper, and display Anaconda white lead made by the electrolytic process, and Anaconda fertilizer, the treble superphosphate, containing 48 per cent P_2O_5 . The products of the following subsidiaries will also be shown: Anaconda Lead Products Co., Anaconda Rolling Mills Dept., International Smelting Co., Raritan Copper Works and United Metals Selling Co. Represented by S. Skowronski and J. A. Dowdy.

ANGEL, H. REEVES, & Co.

ANTI-CORROSION ENGINEERING Co., INC.—Apparatus for treating water so as to make it non-corrosive to iron and steel pipe, tanks and other equipment. Represented by J. Wright Reeve and A. B. Christen.

ANTI-HYDRO WATERPROOFING Co.—Protective covering for concrete and cement masonry which is subject to direct contact with acids, alkalis, oils and various chemicals. Represented by B. A. Meyer, M. W. Meyer, Mrs. M. D. Hausling, T. Moore, W. C. Kober, C. A. Brown, M. E. Townsend and B. E. Lamphier.

APEX CHEMICAL Co., INC.—Industrial chemical products for the textile, leather and fur-dyeing industries and the manufacture of rubber, printing ink and allied products. Represented by S. M. Hermann, Hugo Helburn, Charles B. Rasenberger and Herman Rothstein.

ARKELL SAFETY BAG Co.—Elastic paper linings for barrels, bags, boxes and drums. Represented by P. J. Morales.

ARMSTRONG CORK Co.—Insulating brick to prevent loss of heat from furnaces, ovens, boiler settings, kilns and other high-temperature equipment; insulation covering for high-pressure and superheated steam lines, tanks, feed-water heaters, evaporators, electrically-heated ovens and hot surfaces; and cork coverings for brine and ammonia lines, cold-storage rooms and other installations where low and constant temperatures are required. Represented by S. L. Barnes.

ARNOLD, HOFFMAN & Co., INC.—Oils, water softeners, gums, starches, dextrines, pigment colors, caustic soda and liquid chlorine. Represented by H. H. Hall, W. R. Metcalfe, C. L. Berntson, G. D. Curtis, H. P. Geier and E. Siedenburgh.

ATLANTIC ENGINEERING Co.

ATLAS ELECTRIC DEVICES Co., INC.—Apparatus for testing colored, printed and dyed material against the fading action of sunlight. Represented by C. W. Jameson and H. S. Thayer.

ATOMIZED PRODUCTS CORPORATION.

AVERY ROCK SALT MINING Co.

BACHMEIER & Co., INC.—Applications and methods for the practical uses of dyes, including the exhibit of a new wood pulp paper card, and silk, leather, acid and chrome woolen sample cards. Represented by W. C. Baur, H. A. Tourrelle, William Lindemann, Henry J. Repp, G. Marston Lord and Henry Gettler.

BAINSON Co., THE.

BAILEY METER Co.—Various types of Bailey fluid meters for measuring steam, water, gases and chemicals; V-notch weir meters having capacity of 60,000 lb. per. hr.; specific gravity recorders, draft gages and a differential gas pressure recorder accurate to 1/10,000 in. of water. Represented by E. G. Bailey.

BAKER & Co., INC.—Platinum laboratory ware and apparatus for chemical purposes; platinum, gold and silver and other precious metals. Represented by E. H. Pelletreau, H. Klausmann and Harold Whitehead.

BAKER, J. T., CHEMICAL Co.—Exhibit of "Baker's Analyzed Chemicals." Represented by W. P. Fitzgerald.

BAKER, JOSEPH, SONS & PERKINS Co., INC.—Laboratory and commercial mixing machines for dry powder and liquid work. Represented by A. Vollrath, J. C. Caley and S. D. Gridley.

BARBER ASPHALT PAVING Co.—Acid-proofing qualities of mastic flooring and exhibits of native lake asphalts and compounds. Represented by F. F. Massey, Theodore Thomas, C. N. Forrest, J. S. Miller, J. A. Topping, H. C. Hottel and F. J. O'Neill.

BARRETT Co., THE.—This company's exhibit will form a part of the general exhibit of the Allied Chemical & Dye Corporation.

BAUSCH & LOMB OPTICAL Co.—Chemical, metallurgical and binocular microscopes, metallographic equipment, optical measuring instruments, including colorimeters, refractometers and saccharimeters. Represented by C. L. Oswald and E. H. Anthes.

BEACH-RUSS Co.—High vacuum pumps, heavy liquid pumps, acid pumps, rotary air compressors and gas boosters. Represented by H. C. Russ and C. A. Beach.

BECKER, A. J.—Special types of carboy carriers and wooden carboy packages. Represented by Messrs. Becker, Barnes, Chuster and Boon.

BECKER, CHRISTIAN, INC.—Analytical chainomatic balances, specific gravity chainomatic balances, bullion and torsion scales. Represented by W. C. Symington, A. T. Millroy, J. W. Wetz, J. K. Dunn and S. W. Hess.

BECKLEY PERFORATING Co.—Perforated metals, welded tanks, sheet metal work, perforated monel metal agitator and coil tanks and monel metal varnish kettles. Represented by F. P. Huston, T. R. Harvey and T. P. Carlson.

BELLE ALKALI Co.—This company's products are exhibited in the booth of Arnold, Hoffman & Co., Inc.

BETHLEHEM FOUNDRY & MACHINE Co.—Chemical apparatus such as sulphonators, autoclaves, nitrators, etc., made of special non-corrosive iron. Represented by Robert E. Wilbur, J. George Lehman, A. H. Stevens, R. H. Stevens, A. O. Hartley, George Ettele, S. O. Solt, C. E. Volkhardt and R. W. Fluck.

BLACKMER ROTARY PUMP Co.—Various types of solid and lined rotary pumps. Represented by A. L. Rock and F. F. Goertz.

BLACKISTON'S SON, P., & Co.—Publications on chemistry and allied sciences. Represented by Walter B. Hilt.

BLAW-KNOX Co.—Forge and hammer welding process for the manufacture of homogeneous steel-plate vessels, clam-shell buckets for rehandling material and for excavating, etc. Also a general line of furnace appliances, sectional steel buildings and materials for general construction. Represented by William C. Coffin and D. C. Grove.

BOYER, KIENLE Co., INC.—A complete line of seed and nut oils, together with byproducts. Represented by J. R. C. Boyer and Charles F. Kienle, Jr.

BRISTOL Co., THE—Recording instruments, including pressure and vacuum gages, liquid level gages, thermometers, pyrometers, psychrometers, voltmeters, millivoltmeters, ammeters, shunt ammeters, wattmeters, frequency meters, electrical and mechanical time recorders, etc. Represented by H. L. Griggs.

BRITISH AMERICAN NICKEL CORPORATION, LTD.

BROWN INSTRUMENT Co.—High- and low-temperature measuring instruments, including indicating and recording pyrometers, recording thermometers, resistance thermometers, indicating and recording instruments for pressure, vacuum, time and operation. Represented by J. P. Goheen, G. W. Keller, J. D. Andrews, George Goodman, M. J. Hess, S. G. Ketterer, V. VanVliet and M. H. Leister.

BUCKMAN & PRITCHARD, INC.—Commercial articles made from zirconium silicate, including refractory bricks, cupola blocks, various sized crucibles, spark plug porcelains, high-tension insulators, electric heater units, pyrometer protection tubes and chemical ware. Represented by H. H. Buckman and G. A. Pritchard.

BUFFALO FOUNDRY & MACHINE Co.—A full line of vacuum driers, evaporators, chemical apparatus, sugar apparatus,

etc., showing new developments in Buflovak and Buflokast apparatus. Represented by E. G. Rippel.

BUILDERS IRON FOUNDRY.—Exhibiting a standard Venturi meter outfit consisting of a small Venturi meter tube on discharge from a motor-operated rotary pump; also registering devices and indicating recorders. Represented by C. G. Richardson and D. J. Purdie.

BURRELL TECHNICAL SUPPLY Co.—See exhibit of Mine Safety Appliances Co.

CALCO CHEMICAL Co.

CANADIAN PACIFIC RAILWAY Co.—Exhibiting a colored map showing the industrial resources of Canada.

CARBORUNDUM Co., THE.—Carborundum refractories consisting of brick, tile and shapes, muffles, saggers, etc., made of Carbofrax. Also carborundum refractory cements and a new refractory material which will be known as "Zirfrax." A complete line of abrasive products, consisting of grain, wheels, paper and cloth, rubbing stones, hones, etc., will be exhibited. Represented by C. E. Hawke, C. F. Geiger, S. A. Fenno, J. H. Harriott, W. L. Meek, F. J. Harrington.

CARBROX Co., INC.—An exhibit of carbrox, a vegetable decolorizing carbon used as a substitute for bone black in a great variety of industries. Represented by H. M. Shilstone and O. L. Barnebey.

CARRIER ENGINEERING CORPORATION.—Air-conditioning equipment, including complete automatic temperature and humidity control. Represented by J. E. Bolling, R. T. Tree, A. E. Stacey, Jr., and R. H. Ward.

CASH, A. W., Co.—Exhibiting section models showing internal construction and operation of the company's pressure reducing and regulating valves. Also other steam appliances such as pump governors, fan engine regulators, strainers and relief valves. Represented by Paulsen Spence, R. H. Keith and R. C. Cory.

CELITE PRODUCTS Co.

CENTRAL SCIENTIFIC Co.—DeKhotinsky constant temperature appliances, oil- and fuel-testing instruments, high-vacuum pumps, electrical appliances for the laboratory and various analyzed chemicals. Represented by O. T. Louis and S. L. Redman.

CHADWICK-BOSTON LEAD Co.

CHAPMAN ENGINEERING Co.

CHAPMAN STEIN FURNACE Co.

CHARLESTON INDUSTRIAL CORPORATION.—Exhibits showing the advantages of the City of Nitro, W. Va., as a location for chemical manufacturing plants. Represented by J. C. Hutsinpillar, R. J. O'Brien, M. F. Chase, W. H. Campbell and H. G. Scott.

CHEMICAL COMPANY OF AMERICA.

CHEMICAL EQUIPMENT Co.—Ceco acid-resisting valves, pumps and sprays, vacuum evaporators and tank car unloading systems. Represented by Robert V. Cook, R. T. White, Arthur Wright and C. A. Murphy.

CHEMICAL PUMP & VALVE Co.—Packingless centrifugal pump and valves, and other equipment for chemical manufacture. Represented by A. B. Antisell and F. A. Warter and others.

CHIRIS, ANTOINE, Co.—Synthetic aromatic chemicals, essential oils and perfume and flavoring materials of domestic and exotic origin. Represented by men from the sales department and technical staff.

CLEVELAND-CLIFFS IRON Co.—Photographic views of various manufacturing departments, also samples of various chemical products. Represented by Charles B. Hall, Austin Farrell and E. J. Hudson.

CLIPPER BELT LACER Co.—Three different types of belt lacing machines will be exhibited and also the application of the different sizes of belt hooks to all kinds of belting. Represented by William F. Kall.

COLTON, ARTHUR, Co.—Machinery for pharmaceutical manufacturers. Represented by R. L. Colton, F. X. Roellinger and B. W. Scott.

COMMERCIAL SOLVENTS CORPORATION.—Butanol, acetone and denatured alcohol and the products in which they are used. Represented by P. G. Mumford, H. E. Hall, C. L. Gabriel, Charles Bogin and T. F. Carty.

CONTACT PROCESS Co.—Sulphuric, muriatic and nitric acids, fuming sulphuric acid, oleum, mixed acid and salt cake. Represented by H. von Rucker and J. E. Curry.

CONTAINER CLUB.—Will display corrugated and solid fiber shipping boxes used for packing and shipping, etc. There is also to be demonstrated a device known as the Webb paper and box tester which is used in determining the strength of the board used in the manufacture of the boxes. Represented by J. D. Malcolmson and J. M. Webb.

COOPER HEWITT ELECTRIC Co.—An interesting display of mercury vapor arc lamps, the commercial source of ultra-

violet light, will be shown to illustrate the various applications of the Cooper Hewitt Uviarc lamps. These will include photo-chemical appliances, therapeutic apparatus, water-sterilizing equipment, color-testing instruments and outfits especially designed as a source of monochromatic light for polariscopic, spectroscopic and interferometer work. Represented by L. J. Buttloph and M. B. Firehock.

COORS PORCELAIN Co.—Chemical and scientific porcelain for use in the laboratory control of practically all manufacturing operations. Also porous porcelain mass electrolytic cells. Represented by H. F. Coors.

CORNING GLASS WORKS.—A full line of Pyrex laboratory glassware. A number of experienced glass blowers will be at work making such pieces of laboratory apparatus as is possible under the conditions imposed. Represented by I. B. Cary, K. Kraissl, A. S. Eggleton, F. F. Pfeiffer and G. W. Drake.

CRANE Co.—A full line of pipe, fittings, valves, etc., in iron, steel and brass, and as a specialty their Cranefilt traps and pressure-regulating valves. A motor-operated gate valve will also be among the working exhibits. Represented by W. L. Oswald, William Sink, W. L. Whyte and J. F. Lee.

CRANE PACKING Co.—John Crane metallic packings for steam, air, oil, water and various chemical services, such as the handling of dilute or concentrated sulphuric acid, benzene, acidulated benzene, caustic soda solution, etc., Represented by Julian N. Walton, F. E. Payne and Miss Betty D'Vorin.

DAVISON CHEMICAL Co.—Exhibiting the various grades of sulphuric acid, 16 per cent to 18 per cent acid phosphate, concentrated acid phosphate, magnesium fluosilicate, precipitated silica, pyrites cinder, sintered ore and silica gel. A silica gel absorber and activator will also be in operation, showing the absorbent qualities of this material. In addition there will be a working exhibit of catalytic gel for the conversion of SO_2 to SO_3 . Represented by C. Wilbur Miller, E. B. Miller, W. D. Huntington, J. R. Wilson, A. E. Marshall, W. A. Patrick, B. F. Lovelace, E. C. Holden, P. A. Davis, G. E. C. Connolly, J. B. Thomas, F. E. Wagner and A. Harvitt.

DAVIDSON, M. T., Co.—Pumping engines, condensers, evaporators, etc., used in chemical and allied lines. Represented by John Lowe, William E. Brennan, F. O. Kompass and Thomas J. Rogers.

DE LAVAL SEPARATOR Co.—A special feature will be the exhibit showing the De Laval method of refining cottonseed oil and also of brightening stock manufacture in the petroleum industry. General types of equipment for chemical and manufacturing projects will also be exhibited. Represented by Walter D. Cleary, A. F. Meston, John H. Lisle and Robert Kostelak.

DEPARTMENT OF MINES OF CANADA.—Economic minerals and ores found in Canada, together with some of the more important products manufactured from them. Represented by Robert A. A. Johnston.

DETROIT CHEMICAL WORKS.

DETROIT RANGE BOILER & STEEL BARRELL Co.—A display of "Perfect" metal bilge barrels of the closed type and with full removable heads. There will also be samples of both light and heavy drums and the new friction top Detroit light drum. Represented by W. B. Goddard and C. C. Choate.

DEVINE Co., J. P.—Illustrations of installations of several different types of apparatus, including a large quadruple effect vacuum evaporator having 26,000 sq.ft. of heating surface, a complete installation of a vacuum chamber drier with material being dried on the trays, and complete with the auxiliaries—i. e., surface condensers and dry vacuum pump. Represented by J. P. Devine, L. W. Graves, H. W. How and A. N. Howes.

DIAMOND STATE FIBRE Co.—A full line of vulcanized fiber sheets, rods and tubes, and also a new waterproof insulation, Condensite Celoron. Represented by Charles M. Bogert and E. J. Sniffen.

DINGS MAGNETIC SEPARATOR Co.—Exhibiting the laboratory apparatus known as the Magnetic Tube Analyzer, which is used for determining the amount of magnetic material in any substance which is concentrated magnetically. Represented by A. H. Ackermann, J. E. Randall, E. F. Oates and R. A. Manegold.

DISTILLATION INDUSTRIES, INC.—Exhibiting a demonstration of the Whitaker-Pritchard process of destructive distillation applied to the manufacture of illuminating gas.

DOMINION BUREAU OF STATISTICS.—Statistical charts showing the development in Canada of the chemical and metallurgical industries. Represented by S. J. Cook.

DOMINION WATER POWER AND FORESTRY BRANCHES, DEPARTMENT OF THE INTERIOR, CANADA.—Exhibit showing the

water-power and forest resources of the Dominion of Canada. Represented by W. B. Stokes.

DORR, Co., THE.—Exhibiting working models of the Dorr thickener, classifier, agitator and pumps manufactured by the company. The sewage clarifier and screen for the mechanical screening of municipal sewage and trade wastes will be shown, also a cane sugar juice clarifier and various other pieces of equipment and processes controlled by the company. Represented by G. W. Repetti, Frank Bachmann and F. A. Downes.

DOW CHEMICAL Co.

DRAPER MFG. Co.

DRYING SYSTEMS, INC.—Spray drying equipment for drying of liquids such as chemicals, milk and food products. Represented by F. A. Lippert and C. H. Currier.

DU PONT, E. I., DE NEMOURS & Co.

DURIRON Co.—Centrifugal and reciprocating pumps, exhaust fans, kettles, valves, cocks, pipe and fittings, laboratory apparatus and various other equipment designed to carry corrosive materials. Represented by M. W. Smith, W. E. Pratt, R. H. B. Elkins, E. A. Suverkrop and T. Jabine.

EAGLE-PICHER LEAD Co.—Lead pigments, lead pipe, lead castings and other specialties; lithopone, zinc oxide, slab zinc and model sublimed white lead plant will also be exhibited. Represented by J. R. MacGregor, H. Gates, C. E. Gilson, W. Van Berlo, H. B. Taylor and D. T. Eastman.

EAST JERSEY PIPE Co.—Hercules-Electric hydro extractors and electric extractors. Represented by H. H. Stephens and J. L. Haring.

ECONOMIC MACHINERY Co.

ECONOMY ENGINEERING Co.—Standard and specially designed portable elevators, tiering machinery, barrel storage racks, etc. A feature will be the recently developed hand-electric portable elevator or tiering machine. Represented by T. R. Tordoff, T. A. Duffey and L. H. Liebel.

EDGAR BROS. Co.

EGYPTIAN LACQUER MFG. Co.—Various articles upon which lacquer and lacquer enamels have been used to produce or preserve the finish. Represented by Charles Schlott, Frank G. Drake, C. E. Hayward and B. Popper.

EIMER & AMEND.—Bingham & Green viscometer and plastometer, Brooks rotating autoclave, calorimeter accessories, E. & A., A. D. L. and Whatman filter papers, mercury sealed stopcocks, electric titration apparatus, Fisher thermometer, Fleming and Fisher combustion bulbs, Freas ovens, balances, hot water mixers and water stills, Gramercy reagent bottles, Hortvet cryoscope, hydrogen-ion apparatus, MacMichael viscosimeter, microscopes, refractometers, colorimeters, Pickel extraction apparatus, replaceable unit furnaces and hot plates, and U. S. Navy emulsifier. Represented by Theodore Taistra, assisted by Messrs. Grille, Fisher, Chalfont, Banner, Churchill, Shulenberger, Eimer and Amend.

ELECTRO BLEACHING GAS Co.—Exhibit of liquid chlorine and of textiles and pulp bleached with this product. Represented by S. W. Jacobs, James B. Duggan, G. R. Ellis, W. J. Weed, W. A. Kennedy and D. K. Bartlett.

ELECTRO CHEMICAL SUPPLY & ENGINEERING Co.

ELECTROLYTIC ZINC Co.

ELMORE, G. H.—Continuous centrifugal driers, acid-resisting centrifugal pumps and various equipment for ore dressing and coal washing. Represented by R. C. Comley.

ELYRIA ENAMELED PRODUCTS Co.—Glass-enameled cast-iron apparatus for chemical manufacturing purposes. A complete glass-lined still set up with a hot oil circulation system for high-temperature work will also be exhibited. Represented by W. E. Gray, Jr., R. W. Smith, D. B. Etters, S. A. Smith, W. I. L. Duncan, E. P. Poste and M. Donauer.

EMPIRE LABORATORY SUPPLY Co.

ENGELHARD, CHARLES, INC.—Le Chatelier pyrometers, electric resistance thermometers, Unicurve base metal couples, automatic temperature and pressure controllers, Impervite porcelains and electric furnaces. Represented by C. W. Hubbard and D. S. Bessemer.

EVERLASTING VALVE Co.—Various types of valves for special valve service. Represented by E. N. Corning, S. E. Carman, D. A. Jenkins and F. S. Schultz.

FEDERAL PHOSPHORUS Co.

FLEISHER & Co., W. L., INC.—Exhibiting a spray drier in operation, with samples of various materials which have been spray dried; also air-conditioning apparatus. Represented by W. L. Fleisher, A. W. Lissauer, R. E. Keyes, D. L. Connelly and S. W. Fletcher.

FLETCHER WORKS, INC.

FLORASYNTH LABORATORIES.

FOUNDATION OVEN CORPORATION.

FOXBORO Co., INC.—Indicating and recording instruments such as thermometers, gages, carbon dioxide recorders,

liquid level gages and temperature controllers. Represented by W. W. Patrick and Clarence Fuller.

FREEMPORT SULPHUR Co.

FUEL PRODUCTS CORPORATION.

GARRIGUES, INC.

GEIGY Co., INC.

GENERAL BAKELITE Co.—Bakelite raw materials and the following finished products made from them: Agitators, airplane propellers, beads, bowling, billiard and pool balls, bushings, camera frames, dental lamps, distributor heads, electric drill parts, fire extinguishers, gears and pinions, impregnated fibers, instrument tops and handles, insulators, jewelry, knife-handles, oil-test cups, ornaments, pipe stems, pistol grips, switch blocks, telephone instruments, water ozonator parts, welding goggles, wire insulation and wireless apparatus.

GENERAL CERAMICS Co.—A complete line of chemical stoneware, standard shapes and forms of fused silica, and a display of magnesia ware. Represented by P. C. Kingsbury, Hubert Royer, K. J. Peters, J. F. Curran, R. S. Beecher and Lucy Walters.

GENERAL CHEMICAL Co.—This company's products will be exhibited in one of the booths constituting the Allied Chemical & Dye Corporation's exhibit. Baker and Adamson laboratory chemicals and the Herreshoff roaster furnace will be shown. Represented by G. G. Ackerson, J. M. Keating, G. N. Vardy, J. E. Wilson, W. J. Kramer and W. R. Chappell.

GENERAL ELECTRIC Co.—The features of the exhibit will be an automatic arc welding outfit and a 50-lb. brass-melting furnace. Furnace exhibit will comprise a semi-cylindrical furnace, a small toolroom muffled arc furnace used for treating tool steel, etc., in the shop, a soldering iron furnace for medium and heavy duty irons, and an automatic control board for a single electrode furnace for sixty-cycle, 230-volt operation. Represented by L. W. Shugg.

GENERAL FILTRATION Co., INC.—Exhibiting Filtrons acid-proof artificial stone filter plates in various shapes and grades and in models showing commercial installations; also exhibiting Electro-Filtros, the acid-proof diaphragm. Represented by F. E. Leiby and W. W. Robacher.

GEORGIA LEAD WORKS.

GIBSON & PRICE Co.—This company's exhibit is a part of that of the United Lead Co.

GLAMORGAN PIPE & FOUNDRY Co.—The exhibit will consist of the following apparatus: A standard direct-motor-driven nine-compartment rotary vacuum filter, a standard duplex direct-motor-driven vacuum pump, a 3-in. high-frequency turbine pump, direct-motor-driven, a standard direct-motor-driven caustic flaker, and a working model of a continuous discharge gas-fired vertical limekiln. Represented by C. H. Hinnant.

GLENS FALLS MACHINE WORKS.—Iron, brass and bronze foundry, paper and pulp machinery. A feature of the exhibit will be the rotary sulphur burner. Represented by O. J. Mills and Frederic S. Chaffee.

GOULDS MANUFACTURING Co.—Exhibiting a line of reciprocating, centrifugal and rotary pumps. Represented by H. R. Gumbert, H. J. Angell, W. J. O'Neill and E. E. Brereton.

GRAVER CORPORATION.—Exhibiting models of water-softening equipment, water-filtering equipment and photographs of acid, chemical and oil storage tanks; also other installations of special steel plate work. Represented by K. W. Bartlett and John J. Felsecker.

GRINNELL Co., THE.

GRINNELL Co., DRYER DIVISION.

HANOVIA CHEMICAL & MANUFACTURING Co.—Quartz glass laboratory wares, special apparatus of quartz glass for laboratory processes, electric resistance furnaces for laboratory use, mercury-vapor arc lamps for various chemical processes—e.g., bleaching, dyeing and testing of colors, oils, etc., Laboratory thermometers with platinum spiral inclosed in quartz glass. Represented by F. W. Robinson, J. P. Rainbault, A. L. Schweickart, C. C. Minter, J. W. Kolbert and E. Simmonds.

HARDINGE Co.—Conical ball and pebble mills as used for crushing, grinding and pulverizing will be shown with the accessory parts necessary for different classes of operation. The application to chemical industrial and metallurgical processes will be illustrated. A feature of the exhibit will be a full working size mill set up completely and equipped with all necessary accessories including chain drive and electric motor. Represented by William H. Baker, H. W. Hardinge, Harlowe Hardinge, R. B. T. Kiliani, V. A. Stout, Robert S. Schultz, Jr., G. F. Metz, Alden Crankshaw and James G. Parmelee.

HAUSER-STANDER TANK Co.—Exhibiting a cylindrical

shaped agitator tank designed especially for chemical use; also a rubber-lined cylindrical tank for the storage of muriatic acid. Other equipment of interest to users of wooden tanks will also be exhibited. Represented by S. Hauser, Jr.

HAYNES STELLITE Co.

HAYS, JOSEPH W., CORPORATION.—Exhibiting various forms of combustion efficiency apparatus such as draft and pressure gages, gas analyzers for flue gas analysis and other special purposes, automatic carbon dioxide and draft recorders and a new float-type recording draft gage for ranges below 3 in. W.

HEPWORTH, S. S. Co.

HERCULES ENGINEERING CORPORATION.

HEYDEN CHEMICAL Co.

HOOKE ELECTROCHEMICAL Co.—An exhibit of the various chemicals that can be manufactured electrolytically from salt, with various samples of caustic soda, bleaching powder and liquid chlorine. Represented by W. H. Chamberlain, B. K. Hotchkiss, G. F. Reale and W. J. Smith.

HUFF ELECTROSTATIC SEPARATOR Co.—Exhibiting a Huff electrostatic separator showing the purification of rock salt, mica, feldspar and fluorite; also a Plumb pneumatic jig for concentrating various ores. Represented by H. B. Johnson, F. R. Johnson and William E. McKee.

HUNGERFORD, U. T., BRASS & COPPER Co.

HUNTER DRY KILN Co.—Exhibiting a model of the Hunter drying system which illustrates the principle of utilizing humidity in connection with drying. Represented by Harry Hunter, O. M. Ragsdale and A. B. Stonex.

HUYCK, F. C., & SONS.—Operating the Kenwood Mills. Exhibiting Kenwood all-wool filter cloth. Represented by E. A. Rees and G. L. Gundel.

HUYETTE, PAUL B., Co., INC.

ILLINOIS ZINC Co.

INDUSTRIAL FILTRATION CORPORATION.—Exhibiting a continuous rotary filter in operation with the necessary tanks and pumps, a small-size continuous rotary hopper dewaterer, and a model of the open-tank type of filter. Represented by William H. Harding, George D. Dickey and Harry W. Conrad.

INNIS, SPEIDEN & Co., INC.—Will exhibit a complete line of industrial chemicals, including photographic chemicals, dye intermediates, talc, casein and milk products and various heavy and fine chemicals of domestic and foreign origin. Represented by E. H. Manahan, H. G. Mackelcan and C. L. Speiden.

INTERNATIONAL CARBON PRODUCTS Co.—Graphite products, the crude ore, from which domestic flake is manufactured into products suitable for crucibles, foundry facings, paints, pencils, batteries, electrodes, water compounds and packing. Represented by H. B. Johnson and Charles D. Burrage, Jr.

INTERNATIONAL COOPERAGE Co., INC.—Exhibiting a complete line of tongued, grooved and plain barrels, such as are particularly adapted to the shipment of dry chemicals, lime, plaster, cement, paste and plastic materials. Represented by B. E. Cuthbert and E. H. Kattman.

INTERNATIONAL NICKEL Co.—Various forms of monel metal partly and completely fabricated with particular attention to its application in the chemical industry. Represented by G. A. Wotherspoon and E. A. Turner.

INTERNATIONAL SALT Co. OF NEW YORK.—Exhibiting various kinds of salt used for chemical purposes. Represented by W. T. Chisholm, George A. Walter and H. J. Osborn.

INTERNATIONAL SMELTING Co.—See exhibit of Anaconda Copper Mining Co.

IRVING IRON WORKS Co.—Exhibiting metallic fireproof ventilating flooring and steps. Represented by Walter E. Irving, Paul Leon Price, W. H. Roope, H. H. Schuldt, J. M. Madden and H. H. Bunker.

ISKO BAUTZ Co., INC.—A display of water floated silica and soft silica of various grinding and consistencies.

ISKO CHEMICAL Co., INC.—Caustic soda and chloride of lime. This company's products and those of the preceding company are exhibited by Innis, Speiden & Co., Inc.

JEWELL POLAR Co.—A display of water-distilling equipment of laboratory and industrial types. Represented by A. C. Jewell, J. H. Needler, R. E. Henry and C. Munson.

K-B PULVERIZER Co., INC.—Exhibiting Pulverburner, a coal-pulverizing and burning equipment and a standard K-B hammer mill. Represented by A. J. Barnebl, Jr., E. H. Brown and J. K. Blum.

KELLOGG, THE M. W. Co.—Exhibiting high-pressure autoclaves, direct-fired kettles and various other chemical equipment manufactured from Kellogg forge-welded steel "Chemi-Steel." Represented by H. Le Roy Whitney.

KENART SYNTHETIC PRODUCTS Co.

KENNEDY VALVE MFG. Co.

KEWAUNEE MFG. Co.

KIEFER, KARL, MACHINE Co.—Exhibiting bottle-rising, filling and corking machines, filling and packaging equipment, filters and pumps. Represented by E. E. Finch, A. J. Sterling and Matt C. Finn.

KLIPSTEIN, A., & Co.—A display of industrial chemicals, colors, dyestuffs, varnish colors, tanning materials, oils and waxes. Represented by A. Klipstein, Jr.

KNIGHT, MAURICE A.—Exhibiting acid-proof chemical stoneware of all shapes and sizes. Represented by Maurice A. Knight, Charles Dennison, Samuel J. Baril, G. Gordon Urquhart and Percy Sawyer.

KOPPERS Co., THE.—Exhibiting a miniature model of a battery of byproduct coke ovens and of various improved types of gas governors and continuous tar stills. Represented by Charles R. Meissner and D. E. Price.

KOPPERS PRODUCTS Co.

KOVEN, L. O. & BRO.

LAKE ERIE CHEMICAL WORKS of the General Electric Co.—Exhibiting tungstic acid, sodium tungstate, tungsten metal powder, mango powder (iron manganese oxide), opaque glass enamel and finish. Represented by W. S. Murtfeldt.

LAMIE CHEMICAL Co.

LEAD-LINED IRON PIPE Co.—Exhibiting lead-lined iron pipe, fittings, valves, stop cocks and block-tin-lined iron pipe and fittings. Represented by Daniel H. Regan, Harry F. Peck, Thomas E. Dwyer and Joseph C. Huestis.

LEEDS & NORTHRUP Co.—The exhibit comprises pyrometers of the potentiometer type, indicating, recording, signaling and controlling, and electrical instruments for the determination of the chemical conditions of solutions by the measurement of electrolytic conductivity of hydrogen-ion concentration. Represented by O. Brewer, C. R. Cary, E. H. Day, G. H. English, E. B. Estabrook, E. A. Keeler, R. D. Milner, A. M. Redding, G. W. Tall and P. H. Taylor.

LEFRANC CHLOROZONE WORKS.—Exhibiting the Schwenk carboy filter. Represented by L. W. Schwenk, V. E. Schwenk, R. F. Rutledge and W. P. Joerger.

LEWIS, GREEN, MCADAMS & KNOWLAND—Displaying a typical experimental drier such as has been successfully used for the solution of a number of drying problems. Represented by R. G. Knowland and John H. Holton.

LIBERTY BY-PRODUCTS WORKS, INC.—A display of various chemicals, soaps and oils. Represented by E. J. Zillessen, W. H. Zillessen, A. D. Washington and A. Naab, Jr.

LIQUID CARBONIC Co., THE—Displaying cylinders containing 99.9 per cent CO₂ connected to a 6-drum outfit, such as is used by many chemical industries. Represented by E. D. Hale, C. S. Wheaton and L. W. Greiner.

LITTLE, ARTHUR D., INC.—Exhibiting the following limited number of subjects as examples of this organization's work in the fields of chemistry, engineering and business management. A silk purse made from a sow's ear, a new plywood glue developed in their laboratory and now made under their technical supervision, single coat gray enamel ware produced for a leading manufacturer. "A. D. L." quantitative filter paper. Process exhibit, separation of zinc from complex ores, and a study of available economies in the fuel situation. Represented by Robert F. La Baron and Frank Farley.

LUNG MOTOR Co.—Exhibiting a simple resuscitating device for use in cases of gas or fume or smoke poisoning, or in apparent drowning or in electric shock collapse, etc. Represented by L. D. Jones and Max Jacobson.

LUNKENHEIMER Co., THE.—The display will consist of valves, boiler mountings, oil cups, grease cups, lubricators, oil pumps and similar products used in the engineering field. Valves constructed of bronze, nickel alloy, cast iron, Monel, electric furnace cast steel and special non-corrodible alloys adapted for the chemical industries will be shown.

LUZERNE RUBBER Co.—Exhibiting a general line of hard rubber articles, especially adapted for use in the handling of acids or corrosive liquids. Represented by H. E. Case.

MAAS & WALDSTEIN Co.—This company will have two exhibits, one of lacquer and lacquer enamels and the other of leather solutions with samples of lacquer and lacquer enamel, and wood and metal finished with these materials. Represented by H. C. Flanigan, C. Frey, G. J. Karl, W. S. Elwin, J. A. Weiss, S. L. Dickinson and H. E. Maynard.

MAGNA METAL CORPORATION.

MAGNESIA ASSOCIATION OF AMERICA.—Exhibiting samples of 85 per cent magnesia pipe and boiler covering, magnesia blocks and lagging for hot steam surfaces, magnesia plastic, and samples of carbonate of magnesia. Represented by C. J. Stover and G. S. Stuart.

MANHATTAN RUBBER MFG. Co.—Exhibiting hard-rubber-coated blowers and pipe and equipment, including a hard-rubber-coated centrifugal in operation. Also transmission belting, conveyor belting and rubber hose of all kinds. Rep-

resented by W. A. Pritchard, Harry Snyder, W. L. Sturtevant and others.

MANNING, MAXWELL & MOORE.

MATHIESON ALKALI WORKS.—Exhibiting soda ash, caustic soda, bleaching powder, liquid chlorine, bicarbonate of soda, sesquicarbonate of soda, and various chlorine solvents, such as tetrachloride, ethylene chloride, etc. Represented by John A. Kienle, John W. Boyer, B. T. Brooks, H. M. Mabey, J. H. McMahon, E. E. Routh, J. A. Rose, W. D. Marshall, R. J. Quinn, R. C. Staples, R. A. McMichael, L. R. Yancey, G. N. Davis and J. B. Peake.

MEAD & Co.—Grinding and pulverizing mills including the small sized Mead mill for laboratory and small production purposes. Represented by Paul O. Abbe, Inc.

MERCK & Co.—Exhibiting a general line of fine chemicals, particularly medicinals and pharmaceuticals. A feature of the exhibit this year will be the large number of useful salicylates, such as salicylic acid, sodium salicylate, methyl salicylate, phenyl salicylate, etc.

MERRILL Co., THE.—Exhibiting the Merco Nordstrom plug valve. Represented by H. P. MacGregor.

METALS DISINTEGRATING Co., INC.—The following products will be exhibited: Zinc dust, tin dust, lead dust, aluminum powder, magnesium powder, copper powder and nickel powder. Represented by S. G. Schatzberg, D. A. Morris, E. J. Hall and P. V. Dair.

MIDLAND CHEMICAL Co.

MINE SAFETY APPLIANCES Co.—Exhibiting different types of the Burrell industrial gas masks, such as are used by fire fighters, steel workers, operators of gas producers and in other industries where carbon monoxide is met. There will also be shown a simple device which indicates immediately the presence of carbon monoxide gas. Other safety equipment such as oxygen-breathing apparatus, electric lamps, gas indicators, first-aid outfits, steel signs, etc., will be shown. Represented by G. H. Burrell, J. L. Lehman and H. J. Segrave.

MINERAL POINT ZINC Co.

MOJONNIER BROS. Co.

MONARCH MANUFACTURING WORKS, INC.

MONO CORPORATION OF AMERICA.—Exhibiting automatic analytical and recording apparatus for the analysis of oxygen in hydrogen gas, hydrogen in oxygen gas, chlorine in chlorine gas, carbon monoxide in producer gas and sulphur dioxide for the sulphite industries. Represented by F. D. Harger and Albert Saunders.

MONEL METAL PRODUCTS Co.

MONSANTO CHEMICAL WORKS.

MORSE CHAIN Co.—Exhibiting a number of samples of different size chains, showing the Morse rocker joint, ranging in size from $\frac{3}{8}$ -in. pitch to 3-in. pitch and in several widths illustrating the chain as used for $\frac{1}{2}$ hp. to 5,000 hp. Represented by R. G. Anderson and various members of the sales staff.

MOTO METER Co., INC.—Exhibiting the Boyce Moto-meters, with particular emphasis on their application to industrial uses, such as the indication of temperature in chemical vats, tanks, ovens and drying rooms, coal piles, refrigerators, kettles and pasteurizers, etc. Represented by J. C. Elverson.

MOTT, THE J. L., IRON WORKS.—Exhibiting acid-resisting enameled cast-iron kettles, stills and autoclaves, and also furnaces suitable for their mounting. Represented by J. J. Blackmore, and T. H. Blackmore.

MULTI METAL Co.—A display of wire cloth in brass, copper, bronze, Monel metal, steel and tin coated wires, also metallic filter cloth, a complete line of standard laboratory testing sieves, and samples of wire cloth ranging from No. 2 mesh up to No. 300 mesh. Represented by Siegfried Stern, Frederick Stern and S. Pullman.

NASH ENGINEERING Co.—Hytor air compressor and vacuum pump, Jennings return-line heating pump, drier exhaust unit, centrifugal pump and sump pump. Represented by Irving C. Jennings, R. H. Carpenter, H. M. Wylie and G. B. Wright.

NASSAU VALVE & PUMP CORPORATION.—Exhibiting the Chemetal acid-resisting valves and centrifugal pumps. Represented by A. T. Haviland, C. Schmitt, J. Figel and B. W. Dezotell.

NATIONAL ANILINE & CHEMICAL Co., INC.—The exhibit of this company will be especially artistic in design, and the decorative effects have been carefully considered in order to show the avenues of usefulness for this company's dyes. A feature of the exhibit will be a colorist's laboratory, in which dye testing will be done.

NATIONAL BINDING MACHINERY Co.

NATIONAL FILTER CLOTH & WEAVING Co.—Different styles and weaves of cotton filter cloth for various filter presses.

Represented by M. W. Smith, E. Boffin, L. R. Prior, T. Moors and T. Dunn.

NATIONAL GUM & MICA Co.

NATIONAL LIME ASSOCIATION.—The association will exhibit a model of a lime plant, charts showing the operations in lime manufacture and the distribution of the uses of lime, together with various materials, such as glass, leather and lime stucco panels, which are made with the use of lime. Represented by M. E. Holmes.

NATIONAL RESEARCH COUNCIL.—An exhibit intended to show the necessity for fundamental chemical research, and the relation of organic chemistry to peace- and war-time industries. Represented by H. E. Howe, H. S. Kimberley and O. E. Roberts.

NATIONAL ROSIN OIL & SIZE Co.—Exhibiting various grades of rosin oil and pitches such as are used in the manufacture of greases, printing inks, canvas belting, waxes, paper cables and brushes. Represented by Richard Bender.

NEWARK WIRE CLOTH Co.—A display of wire cloth of all grades, metallic filter cloth and testing sieves. Represented by A. A. Campbell, L. C. Campbell, J. C. Campbell and E. J. Korn.

NEW BRUNSWICK CHEMICAL Co.—Exhibiting a general line of textile soaps, sizings and finishes, also terpol hydrate, which is a special warpsizing made by this company.

NEW ENGLAND TANK & TOWER Co.—This exhibit will show a complete outfit, in operation, including tank, stirrer and direct-connected motor-driven agitator. Different types of stirring equipment and of apparatus for transporting semi-liquids and liquids will also be shown. Represented by Arthur E. Hall, George E. Hall Conrad Pennucci and Warren O. Chace.

NEW METHOD UTILITIES Co.—Exhibiting photographs and working drawings of a refrigerating and ice-making system without moving parts, which has recently come into use in chemical plants. Represented by B. K. Nagel and H. A. Leeuw.

NEW JERSEY ZINC Co.—Besides exhibiting its entire line of zinc products, this company will feature Horse Head rolled zinc for building construction work. Zinc leaders, eaves-troughs, Spanish tiles, flashings, valleys, fittings, etc., installed on an improvised portion of roof, will be displayed. Other zinc products and byproducts will include zinc oxide, slab zinc, zinc dust, Albalith, lithopone, zinc sulphate, feathered zinc, salt cake, sulphuric acid, muriatic acid, and zinc chloride. Represented by W. H. Hendricks, A. E. Mervine, F. C. Ryan, S. C. Reynolds, F. W. Edwards, S. T. Ballinger, C. F. Beatty and H. W. Henderson.

NEWPORT CHEMICAL WORKS, INC.—The exhibit of this company will illustrate its slogan of "Coal to Dyestuff." Represented by Giles Low, J. S. Lange and C. F. Schumann.

NEW YORK CENTRAL IRON WORKS Co., INC.—Exhibiting photographic views of steel tanks, stacks, breechings and chemical equipment of all kinds. Represented by Paul G. Koch, H. M. Olson, C. E. Plack and C. R. Rupp.

NEW YORK JEWELL FILTRATION Co.—Exhibiting the operation of the refiltration system which is applied in paper making and in other industries where the conservation of water is essential. Another feature of the exhibit is various types of chemical feeding devices which are used for regulating the dosage of chemicals in large filtration plants. Represented by A. L. Sollder, Arthur M. Crane, E. K. Sorenson and D. C. Williamson.

NIAGARA ELECTRO-CHEMICAL Co.

NICHOLS COPPER Co.—An exhibit to show the use of copper sulphate (as Bordeaux mixture) in the cultivating of fruit and vegetables; the use of red copper oxide in marine paints, and the production of copper wire and ingot bars, cakes, slabs and cathodes. Represented by G. P. Hitchcock.

NITROGEN CORPORATION.—Exhibiting various products of ammonia made by synthesis from atmospheric nitrogen. Represented by A. Nagelvoort and J. C. Clancy.

NORWALK IRON WORKS Co.—Exhibiting a new Norwalk vertical three-stage oxygen compressor and a multi-cylinder ammonia refrigerating compressor. Represented by A. R. Betts.

OBERMAYER, THE S., Co.—Hott-Patch furnace cement for power and chemical plants. A small electric furnace will be used for demonstration of the product. Represented by E. D. Frohman, F. P. Bullion, H. E. Beckman, J. M. Hildebrand and W. R. Cummings.

OLIVER CONTINUOUS FILTER Co.—Exhibiting a complete Oliver continuous and automatic filter in operation. Represented by H. A. Morrison, C. T. Eastman, C. W. Moore and L. W. Knapp.

PACIFIC COAST TALC Co.—This company's products will be exhibited with those of Innis, Speiden & Co.

PALO Co.—Exhibiting the following apparatus: Hess-Ives tint photometer, American-made spectroscopes and refractometers, Durieux filter paper, analytical balances, Meker burners and various types of furnaces, including those used for high-temperature crucible work and for fusion, heat-treating, annealing, etc. Represented by L. A. Pfluger, H. A. Peterson and M. J. Seavy.

PARKS-CRAMER Co.—Exhibiting a small-size standard Merrill process system such as is used for supplying heat by oil circulation. High-duty humidifier heads and a heat and humidity regulator will also be exhibited. Represented by Alexander B. McKechnie, Thayer Francis, Stuart H. Caldwell, J. W. F. Macdonald, A. W. Thompson and Frank G. Bell, Jr.

PENNSYLVANIA SALT MFG. Co.

PERMUTIT Co., THE.—A display of a model of the Zeolite water softening and filtration equipment manufactured by this company. Represented by A. T. Smith, R. W. Epple, J. S. Shedden and G. E. Boyd.

PERRY & WEBSTER, INC.

PERTH AMBOY CHEMICAL Co. See exhibit of Roessler & Hasslacher Chemical Co.

PFAUDLER Co., THE.—Exhibiting a glass-lined closed jacketed mixer (furnished with an enameled steel agitator) which is used in the manufacture of chemicals, dyes, printing inks, coal-tar products, etc. Other standard glass-lined equipment and accessories will also be exhibited. Represented by R. B. Kilmer, I. E. Colvin, J. A. Cowles, P. S. Barnes, F. J. Bresnan and T. D. Wilson.

PHILADELPHIA DRYING MACHINERY Co.—An exhibit of the various types of Hurricane drying machines, including the cabinet tray drier and truck tray drier. Also a photographic display of various installations. Represented by W. W. Sibson, C. H. Reumann, E. K. Moore and S. Watson.

PHILADELPHIA QUARTZ Co.—Liquid, solid and powdered forms of silicate of soda. Represented by R. C. Brown, W. H. Buxton and A. W. Moore.

PITTSBURGH-DES MOINES STEEL Co.—Exhibiting pictures and blue prints of various installations of structural steel work. Represented by Ivan A. Bickelhaupt.

PNEUMERCATOR Co., INC.—A display of a complete line of gages for the indication of depth, weight, volume or specific gravity of any liquid stored in tanks at any pressure. Represented by H. S. Parks and William Thomas.

POTDEVIN MACHINE Co.

POWER SPECIALTY Co.

POWHATTAN MINING Co.—Asbestos in its various stages of manufacture from the mining of the crude asbestos to the fabrication of the finished product will be exhibited. Represented by Fred A. and Frank Mett.

PRECISION INSTRUMENT Co.—Exhibiting a general line of boiler room and gas plant specialties, including the precision single and multiple indicating and recording gages, combustion recorders, orsats, gravimeter, calorgraphs, etc. Represented by L. D. Vorce, E. C. Rack, Robert Hooper and R. H. Tilghman.

PROCTOR & SCHWARTZ, INC.—Exhibiting a model of the Proctor driers for drying colors, chemicals, raw stock, soap, etc. Samples of all kinds of materials dried in Proctor driers will be exhibited and a projectoscope will show various installations in representative chemical plants. Represented by E. B. Ayres, H. S. Landell, D. D. Hollenbaugh, A. O. Hurxthal and Mrs. A. E. Reiter.

PROVOST ENGINEERING Co.

PYROELECTRIC INSTRUMENT Co.—Exhibiting a line of electrical precision instruments, including pyrometers and apparatus for hydrogen-ion determinations, both electrometrically and colorimetrically. Represented by W. C. Harter and Harry L. Saums.

QUIGLEY FURNACE SPECIALTIES Co.—Materials and equipment for furnace construction and operation, including a high-temperature cement for bonding fireclay and silica bricks and blocks, as well as granular refractories, a specially prepared cellular refractory brick used in insulating furnace structures for the conservation of heat, and a highly refractory fire sand used with a suitable binder for making rammed-in linings for furnaces, special tile, patches and repairs. The Quigley powdered coal system will also be demonstrated. Represented by W. S. Quigley, H. A. Kimber, J. H. McPadden, F. W. Reisman, W. H. Gaylord, Jr., W. A. Toohill and C. C. Gantzman.

RARITAN COPPER WORKS.—See exhibit of the Anaconda Copper Mining Co. for a description of products to be displayed by this company.

RAYMOND BROS. IMPACT PULVERIZER Co.—An exhibit of operating models showing the various types of pulverizers, roller mills and air-separating plants produced by this company. The machines will be in actual operation, grinding

representative materials. Represented by C. M. Lauritzen, W. M. Cook, Joe Crites and S. B. Kanowitz.

RAYMOND LEAD WORKS.—Exhibit with the United Lead Co.

READ MACHINERY Co.—An exhibit of different types of mixers such as are used for mixing pharmaceutical products, pastes, polishes, food products, etc. Represented by D. D. Strite.

REFINITE Co., THE.

RELIANCE GAUGE COLUMN Co.

RHODIA CHEMICAL Co.

ROBERTSON, JAS., LEAD WORKS.

ROESSLER & HASSLACHER CHEMICAL Co.—Exhibiting a large number of chemicals applicable to electroplating, ceramics, mining, cleaning, bleaching, dyeing, oxidizing, paint manufacture, soap making, tanning, rubber industry, hydrogenation, refrigeration, steel tempering and case-hardening, electric cells, fireworks, fireproofing, etc., together with solvents, colors, rare metals, metal oxides, fumigators, insecticide and fungicide products. Represented by Sterling Temple, M. S. Stewart, T. V. Ainslie, F. Abegg and C. S. Williams.

ROTO Co., THE.—Exhibiting a line of tube-cleaning apparatus, which consists of specially designed motors operated by compressed air or steam, equipped with specially designed tools for the removal of deposits from the heating surfaces of tubular apparatus such as steam boilers, economizers, condensers, heaters and other apparatus of a similar character. Represented by W. R. Van Nortwick, W. M. Kelley and J. V. Doherty.

RUGGLES-COLES ENGINEERING Co.—Exhibiting models, photographs and drawings of the various types of driers manufactured by this company. Represented by F. E. Finch, W. H. Glomb and J. K. Towers.

SALMON FALLS MANUFACTURING Co.—A display of Toron-treated fabrics, together with samples of rubber products and insulators which have been manufactured by the use of Toron-treated fabrics. Represented by A. Russell Atwater and W. B. Pratt.

SANDOZ CHEMICAL WORKS, INC.

SANDUSKY COOPERAGE & LUMBER Co.—A complete line of barrels suitable for packing both dry and liquid chemicals. Represented by A. O. Theobald.

SARCO Co., INC.—Sarco temperature regulators for tank, room and kiln control. Sarco steam traps for low and high pressure. The new Sarco radiator trap Type "E" and the new Sarco (Fournier) indicating thermometers for chemical and industrial purposes. Represented by Clement Wells, E. J. Ritchie, G. H. Burke and G. F. Corder.

SCHAEFFER & BUDENBERG.—A complete line of efficiency-promoting instruments, such as indicating and recording gages, indicating and recording thermometers, counters, tachometers, calorimeters, etc. Represented by Messrs. Undeutch, Campbell and Schipper.

SCHUTTE & KOERTING Co.—Complete line of power plant equipment, consisting of: Oil-burning, oil-heating and oil-cooling apparatus; feed-water heaters, injectors, condensers, stop check valves, trip throttle valves, reducing valves and engine stop valves; pump primers, undergrate blowers; also other Koerting steam, water, and air jet appliances, and the Schutte line of lead-lined and special duty valves, which are used in the chemical industry. Multi-jet condensers in operation under vacuum and also open for inspection. Schutte engine stop system with overspeed tripping device also in operation. Represented by Messrs. Kimberly, Gessleman, Philbrook and Keet.

SCHWARTZ SECTIONAL SYSTEM.—Sectional filing cabinets and auxiliary desks for chemical laboratories. Represented by M. P. Schwartz.

SCHWENCK CARBOY TILTER Co.—See Exhibit of Lefranc Chlorozone Works, Inc.

SCIENTIFIC EQUIPMENT Co.—As Eastern Sales Division of Central Scientific Co. and Kewaunee Mfg. Co., will exhibit a representative line of American-made laboratory furniture and apparatus. Represented by J. M. Roberts, S. L. Redman, A. B. Carter, Charles G. Campbell, O. T. Louis, Charles Ress, Edward Breitwieser, Joseph R. Fisher, Theodore Fuchs, Jr., and A. V. Hoveling.

SCOTT, ERNEST & Co.—Photographs showing a number of installations which have been furnished to various trades and are used for reclaiming chemicals of value from factory waste liquor, deposits, etc. The apparatus illustrated by the photographs will consist of: Vacuum evaporators as used by the soap trade for recovering glycerine from waste spent lyes, paper pulp mills for recovering the caustic alkali from waste black liquors, cotton finishers for recovering the caustic from waste mercerizing waters, glue and gelatine manufacturers for concentrating their liquors,

caustic soda manufacturers for concentrating caustic soda liquors, distilled water manufacturers for making pure water from sea, brackish and other waters, packing houses for concentrating tankage liquors, and many other uses; vacuum driers as used by food, paint, salt and other manufacturers; solvent extraction apparatus as used by oil manufacturers for extracting oils from seeds, beans, nuts, etc., also from waste filter press residues, grease from bones, oil from fish waste and other waste oily and greasy materials, such as sewage, wool scourings, packing-house tankage, etc.; ammonia stills for making pure ammonia; and wood-distillation plants. Represented by H. Austin, R. W. MacGregor and C. E. Bradley.

SEMET-SOLVAY Co.—Model of a Semet-Solvay byproduct coke oven, which is complete in every detail. A model illustrating the use of Solvay granulated calcium chloride as a natural dust layer and binder for roads, tennis courts, playgrounds, race tracks, etc. In addition a complete line of products manufactured by the company will also be displayed. Represented by E. C. Scott.

SEYDEL MFG. Co.—Samples of fifty or more benzoates together with literature covering their uses in the fields of medicine and of preserving foodstuffs. Furamine dyes, which are used for dyeing skins and furs. Represented by Edmund E. Smith.

SEYMOUR & PECK Co.—Wooden shipping drums which are used as shipping packages for aniline dyes, dry colors, insecticides and other dry chemicals. Represented by C. B. Arnold and Mrs. C. H. Bacon.

SHARPLES SPECIALTY Co.

SHEFFIELD BY-PRODUCTS Co.—This company's products will be exhibited with those of Innis, Speiden & Co.

SHERWIN-WILLIAMS Co., THE.—The manufacture of paints, varnishes, dyes, chemicals, pigments, coal-tar products, insecticides, etc., will be illustrated by exhibits of important raw materials, samples of the finished product and examples of merchandise finished with these products. Represented by A. W. Steudel, J. O. Hasson, L. D. Walker, A. J. Binder, B. N. Van Cleve and M. K. Barrett.

T. SHRIVER & Co.

SILICA GEL CORPORATION.—See exhibit of the Davison Chemical Co.

SLY, W. W., MFG. Co.

SNYDERFIBA CORPORATION.—Paper barrel and drum making machines in full operation, making barrels and drums in all sizes and diameters from 10 in. up to 19½ in. by 30 in. long, together with a complete display of samples of various packages and different types of heading, as used by customers. Represented by Charles Ashmun and Oscar Duryea.

SOLVAY PROCESS Co. This company's products are shown in the exhibit of the Allied Chemical Dye Corporation.

SOUTHERN COTTON OIL Co., THE.—Products of cottonseed oil and the following byproducts derived therefrom: Cottonseed linters, distilled cottonseed fatty acids, cottonseed pitch and paint products. Represented by W. E. Fackert, Philip Brendel and George J. Drewes.

SOUTHERN RAILWAY SYSTEM.

SOWERS MFG. Co.—Dopp seamless steam and oil jacketed kettles, mixers, vacuum and pressure pans, and soap cutters. Some of this equipment will be in operation. A sawed-up section of a jacketed kettle, showing the seamless construction. Also samples of over 100 different products now being made in Dopp apparatus. Photographs and blue prints of various styles of kettles and agitators, etc. Represented by A. E. Howlett, R. Bellows, Austin M. Kuhns, G. Gordon Urquhart, C. E. Brown and R. C. Boggess.

STANDARD OIL Co. OF N. J., CHEMICAL PRODUCTS DIVISION.

STANLEY, W. W.

STAR BOX & LUMBER Co.

STAR CORRUGATED BOX Co., INC.

STEIN, HALL & Co., INC.

STIMPSON EQUIPMENT Co.—Mitchell electric vibrating screen which is applicable in handling screening problems with crystalline or granular materials. Represented by James A. Lane.

STUART & PETERSON Co.—Chemical apparatus consisting of steam jacketed kettles, steam jacketed vacuum pans, porcelain-lined evaporating pans and chemical storage cans. Represented by H. E. Jacoby and F. P. Kearns.

SULLIVAN MACHINERY Co.—Working models of the Sullivan air lift and displacement pumps. Represented by L. R. Chadwick, John Oliphant and L. E. Gilbert.

SWENSON EVAPORATOR Co.—Swenson evaporators and equipment. Represented by F. M. DeBeers, P. B. Stadler, P. H. Appell, G. Gordon Urquhart and F. F. Mackentepe.

TAGLIABUE MANUFACTURING Co.—Tag-Roesch automatic time-temperature-humidity controller. This device regu-

lates the valves on a heating coil and a spray, so that the humidity is gradually decreased at the same time as the temperature is increased. Easy adjustments enable almost any desired temperature-humidity schedule to be duplicated. Tag automatic controllers of temperature, pressure, vacuum, time, liquid-level and condensation discharge. Tag indicating thermometers, chemical thermometers and hydrometers. Tag recording thermometers with improved operating mechanism, and evenly graduated chart, micrometer per. adjustment, pen chart-pressure adjustment, pen-lifting device, etc. Represented by L. C. Irwin, T. Dougherty, V. Wichum, W. W. White and A. Traudt.

TAKAMINE LABORATORY, INC.—Polyzime and Neco-Malt. Represented by J. W. Coleman, Jr., Milton Tanner and William Newel.

TALC & SOAPSTONE PRODUCERS' ASSOCIATION.—The various kinds of talc and soapstone mined and milled in the United States will be shown. Specimens of the crude talc rocks, ground tales, talc crayons and articles in which talc has been used will constitute the exhibit. The aim of the producers is to call attention to the numerous and growing uses for talc and soapstone in the manufacture of paper of various grades and in textile, rubber, paint, soap, glass, ceramic, linoleum, leather and other industries as well as in the manufacture of toilet preparations.

TANNER, CHARLES S., Co.

TAYLOR INSTRUMENT Co.—A representative line of industrial indicating and recording thermometers and pressure gages, recording and indicating pyrometers, temperature and pressure regulators, laboratory thermometers and hydrometers. Represented by E. N. Huriburt, J. W. Schwarz, F. E. Ely, J. P. Gilmore, H. W. Kugler and Walter N. Maurer.

TECHNICAL PRODUCTS Co.

TEXAS GULF SULPHUR Co., INC.—A special feature of the exhibit will be photographs of sulphur mining. Represented by H. R. Wemple and A. S. Cosler.

THERMAL SYNDICATE, LTD.—Complete line of Vitreosil, laboratory apparatus and plant equipment. Vitreosil will be shown in the transparent, translucent and opaque grades. The special feature of the exhibit will be a new type of distillation unit designed especially for the production of chemicals of high purity but adaptable to many other distillation problems, including those which require fractionating. Complete information can be obtained regarding the use of Vitreosil in sulphuric acid concentration, nitric acid, and hydrochloric acid manufacture as well as in many other specialized uses. There will be on exhibit a design showing a new type of hydrochloric-acid unit in which both the cooling and the absorption of the gas are done in Vitreosil. Represented by W. W. Winship, S. L. Tyler, W. E. Strevg and F. A. Wenman.

THERMO ELECTRIC INSTRUMENT Co.

THWING INSTRUMENT Co.—A full line of temperature measuring and recording apparatus and a line of paper testing apparatus, including basis weight scales, humidometers and tearing testers. Represented by C. B. Thwing, Edward J. Albert, H. K. Walton, J. H. Torrey and J. H. Houghton.

TITANIUM ALLOY MANUFACTURING Co.

TITANIUM PIGMENTS Co., INC.

TOLHURST MACHINE WORKS.—The following motor-driven centrifugals especially prepared for use in the chemical industry will be in operation: A 40-in. Tolhurst heavy chemical type suspended centrifugal with bottom discharge basket; a 48-in. direct motor driven Tolhurst self-balancing centrifugal with tinne'd basket; a 40-in. Tolhurst self-balancing centrifugal arranged for bottom discharge; a 40-in. Tolhurst center slung centrifugal arranged with covered top and bottom especially prepared for handling volatile solvents; a 26-in. Tolhurst motor drive solid curb centrifugal of the open top type, with rubber-lined case and rubber-covered basket; a 12-in. laboratory centrifugal of the semi-commercial type. Represented by W. C. Dutton, John S. Gage, B. M. Pilhashy, W. J. Westaway, T. A. Bryson, T. M. Stuart and R. K. Cheney.

TOWER MANUFACTURING Co., INC.

TYLER, W. S. Co.—Woven wire screen, ton-cap, Hum-Mer electric screen, Ro-Tap testing sieve shaker, Tyler standard screen scale testing sieves.

UEHLING INSTRUMENT Co.—Uehling CO, recording equipment, draft recorders, vacuum recorders, draft analyzers, absolute pressure indicators, combined barometer and vacuum recorders and various other indicating and recording instruments. Represented by F. F. Uehling, C. J. Schmid, C. C. Phelps, R. E. Terhune and H. D. Thomas.

UNION STEAM PUMP Co.—A complete line of pumping machinery for the chemical industry. Union simplex, du-

plex and triplex types of pumps for either steam or power drive. Centrifugal pumps, air and gas compressors, surface and jet condensers. A new improved rotary pump for viscous liquids. Represented by George L. Todd, R. W. Friedman and K. D. Smith.

UNION SULPHUR Co.—Represented by W. N. Wilkinson and W. M. P. Taylor.

UNITED CHEMICAL Co.—This company's products will be exhibited with those of Innis, Speiden & Co.

UNITED FILTERS CORPORATION.—Small models of an American continuous vacuum filter, Sweetland pressure filter, and United plate and frame filter press; also one complete disk and rotary valve from an 8 ft. diameter American continuous vacuum filter and the latest type of roller cake remover for automatically discharging the cake from this type of filter. Represented by Robert C. Campbell, E. J. Sweetland, L. D. Thompson and C. M. Stanley.

UNITED HAMMER Co.—A Fairbanks pulverizing hammer for use in the chemical laboratories in the preparation of pig-iron and other samples for laboratory tests.

UNITED LEAD Co.—A complete line of United acid-resisting products will be shown: Chemical lead tube lined wrought steel pipe, flanged and screwed fittings, chemical lead-lined valves, special apparatus, hard lead and block tin-lined centrifugal acid pumps, block tin-lined pipe, fittings and valves, also chemical lead-lined and covered and block tin-lined and covered special apparatus such as tanks, agitators, autoclaves and evaporators. Represented by George H. Checkley, J. W. Spotten, C. R. Andrews, C. L. Meyer, W. J. Donnan, H. Hempel and F. Freiherr.

UNITED METALS SELLING Co.—See exhibit of Anaconda Copper Mining Co.

UNITED STATES CAST IRON PIPE & FOUNDRY Co.—Details of the manufacture of castiron pipe and large castings will be illustrated by an actual section of flange pipe and pictures showing the history of cast-iron pipe, and modern methods of production. Helander barometric condenser. Represented by H. A. Hoffer, J. C. Capron and C. D. Donaldson.

U. S. BUREAU OF STANDARDS.

U. S. INDUSTRIAL ALCOHOL Co.—Various grades of alcohol and the new product "Alcorub."

U. S. INDUSTRIAL CHEMICAL Co.—Thirty or forty chemical products will be exhibited by this company, among which are distilled iodine, tincture of iodine, ethyl ether, denatured absolute ethyl alcohol, oxalacetic ester, isopropyl ovalate, isoamyl propionate and ethyl isovalerate. Represented by B. R. Tunison.

U. S. STONEWARE Co.—Representative pieces of glazed acid-proof chemical stoneware, including various shapes and sizes of acid containers, pipe lines, mixers, manifolds, faucets, etc. Represented by F. S. Wills, J. J. Chamberlain and G. M. Wills.

VALLEY IRON WORKS.—Laboratory autoclaves and sulphonators of various sizes. Represented by Thomas Senior.

VALLEZ, H. A.—Two Vallez rotary filters will be in operation. Represented by H. A. Vallez and Arthur Vallez.

VAN NOSTRAND, D., Co.—New books and recent editions of standard reference works will be featured and special books relating to pure and applied chemistry will be shown. Represented by E. M. Crane, A. G. Heany and P. H. Healy.

VITREOUS ENAMELING Co., THE.—Vitreous enameled pans and traps for drying drugs, paints and chemicals and food-stuffs. Being non-corrosive, easy to clean and very durable, these pans are well adapted for use in plants where vacuum or shelf driers are employed. Represented by Harry Warman and Charles E. Bullard.

VOLAND & SONS, INC.—Assay, analytical and bullion balances and weights. Represented by George G. Voland, Emil L. Voland, Harry C. Henn, George J. Brentano, John Kisting and John Schwab.

WAILES DOVE-HERMISTON CORPORATION.—Anti-corrosive paints, solutions, enamels, mastics and special bituminous compositions for the protection of iron, steel and concrete exposed to atmospheric moisture, electrolysis, acids, acid fumes, alkalis, sewage, brine, etc., buried in the ground or submerged in fresh, salt or acid water. The products exhibited will include Bitumastic solution, Bitumastic liquid paints, Hermastic and Bitumastic enamel and Hermastic pipe coating. Represented by Willard T. Chevalier and Ray B. Nisbet.

WALLACE, JOSEPH H. & Co., INC.—The exhibit will consist of a stump from cut-over pine lands of the South, surrounded by samples of products which may be obtained from this waste wood. These products include turpentine, pine oil, rosin, tar, pitch, wood pulp, purified cellulose suitable for making gun cotton, kraft paper, fiber board and book paper. There will also be photographs and explanatory

charts. Represented by Messrs. Greenwood, Burleigh and Stevens.

WALLACE & TIERNAN Co., INC.—A general line of chlorine control apparatus, including units for the production of bleaching solutions used in the paper, textile and kindred fields, for the sterilization of water, disinfection of sewage and tannery waste. Chlorine cylinder valves, Venturi type gas flow meters, pressure-reducing valves, etc., for the general chemical industry. Also dry feed equipment for heavy chemicals and the Palmer water spray apparatus for the examination of air. Represented by M. F. Tiernan, W. J. Orchard, L. H. Goebel, R. V. Donnelly, R. V. Henkel, G. D. Peet and J. C. Baker.

WEDGE MECHANICAL FURNACE Co.—Data will be available for answering questions raised by anyone interested in the Wedge mechanical burner. Represented by Leslie H. Webb and Carl S. Fogh.

WESTINGHOUSE ELECTRIC & MANUFACTURING Co.—Automatic regulator and control equipment for steel-refining furnaces. Motors for chemical industry, both a.c. and d.c., together with control equipment. Specially treated coils, George Cutter industrial lighting fixtures for indoor and yard lighting, together with other electrical equipment especially designed for the chemical industry. Represented by G. H. Jaspert, C. B. Gibson and C. G. Schluederberg.

WHEELER, C. H., MANUFACTURING Co.—High vacuum apparatus consisting principally of different types of Radojet air ejectors such as single-stage, double-stage, as well as double-stage with surface inter-condenser types. These pumps have been extensively used in chemical plants in connection with evaporators and stills for producing high vacuum, the advantage being that they have no moving parts, their operation being based on the ejector principle. Represented by Charles Lang and J. Dobson.

WHEELER CONDENSER & ENGINEERING Co.—Evaporator, condenser, circulating pumps, Edwards air pumps, steam jet air pumps, cooling tower and a brass and copper tube exhibit. Represented by J. L. Kretzmer, F. H. Schubart, E. H. Chapin, R. D. Spear and R. T. Erwin.

WHITALL TATUM Co.—An exhibit of glassware and rubber ware from crude material to the finished product, with special emphasis on "Nonsol" chemical glassware.

WHITE, WILBUR, CHEMICAL Co.—This company's products will be exhibited with those of Innis, Speiden & Co.

WHITLOCK COIL PIPE Co.—The exhibit will feature coils and bends made up of iron, steel, copper, brass, aluminum pipe and tubing. Also solvent recovery heaters, coolers, hot-water heaters, high-pressure piping. Represented by William A. Evans, C. I. Babcock, F. J. Brengel, W. C. Beekley and H. J. Anderson.

WILL CORPORATION, THE.—Ion-O-Meter, Will shaking apparatus, Will combination extraction apparatus, Faltin water still, and Will bottle washer are to be exhibited. Represented by William Dalton and R. T. Will.

WILLSON GOGGLES, INC.—Safety goggles and respirators. A new type of safety goggle of much interest to safety men will be shown for the first time. Represented by T. A. Willson and F. M. Rockwell.

WINNER Co., THE.—A demonstration of the Winner steam trap. Temperature control regulators for steam, hot water and ammonia. Winner boiler compound. Represented by Allen A. Smith, Thomas W. Monahan, R. Fruiesen and F. L. Valliere.

WINSLOW & Co., INC.—A full line of acid-resisting brick and shapes. Represented by E. H. Winslow.

WOLF, JACQUES, & Co.—Sizing and finishing materials, colors and mordants for fabric printing, hydrosulphite for discharge printing and stripping, textile gums for printing and finishing, soluble oils, softeners, and Monopole oil. Samples of silk, cotton and woolen fabrics printed and finished with these materials. Represented by S. E. Tylee, Jr., and others.

WORTHINGTON PUMP & MACHINERY CORPORATION.

YALE & TOWNE MANUFACTURING Co.—A model A-17 crane truck and a model C-6-36 trailer. These two units will be used to move the greater part of the material being exhibited from the receiving platform to the various booths. Represented by C. T. Gies, H. C. Yost and J. C. Morgan.

YOUNG BROS. Co.

ZAVON Co., INC.—Zavon, a textile solvent used in the cotton, silk, woolen and fur industries. Represented by George A. Reeder, Esther C. Cannon, John Stokes, C. C. Harding, L. W. Kearns and C. A. Aeschmann.

ZELLER LACQUER MANUFACTURING Co., INC.—Lacquers, thinners, lacquer enamels, bronzing liquids, solvents and solutions, as well as the finishes obtained through the uses of such products. Represented by Hugo, Richard, and Gustav Zeller.

HUMAN WASTE
THE FOUNDATION OF PRODUCTION

From "Industrial Medicine and Surgery,"
Saunders Pub. Co., Philadelphia.

Human Waste in Industry

Strong Emphasis Is Placed on the Role of the Physician in Industrial Plants,
With an Outline of the Preventive and Curative Medical Services
Which Can Be Rendered to the Working Forces in Industry

By HARRY E. MOCK, M.D.
Fellow American College of Surgeons

THE physician and the engineer are joining hands in the fight against industrial waste. For the first time in the history of our nation professional fences are being torn down. Every individual, group or national organization fitted by training or experience to help in this fight are being called to the colors. Most of the problems of the engineer deal with the physical properties of the plant, the machinery and many of the economic equations of management, while most of the problems of the physician in industry deal with the physical phases of the life of the working force, both in the plant and in the home. The importance of the civil, the mechanical, the electrical, the chemical and every other type of engineer to industry has been recognized for generations. Today the human engineer is likewise becoming an important factor in industry.

CO-OPERATION BETWEEN ENGINEERS AND PHYSICIANS TO CORRECT HUMAN WASTE

The nation in its rapid industrial development has been prodigal with its natural resources. No greater example of this prodigality can be found than in the wasteful attitude toward human life and limb. The concerted effort now in progress to correct industrial waste promises to accomplish the greatest reforms in public health, the prevention of disease and accidents, the medical care of the working people and other

human conservation measures ever witnessed in this country.

Surveys and scientific research! Make a survey and learn the size of the problem! Search and research for the scientific principles, both in engineering and in medicine! These and similar slogans during the last several years have resulted in the accumulation of a mass of information and material. We are now entering upon a period of practical application of these principles to the everyday problems of existence.

DOCTORS' OFFICES ARE RECENT ADJUNCTS TO INDUSTRIAL PLANTS

Universities and colleges, noted for centuries as storehouses of knowledge, are now becoming reservoirs of service to the people. To have a part in this greatest of all conservation movements is an honor to be sought for, and medicine with its various specialties is ready and anxious to co-operate.

The years 1909-10 mark the first concerted movement on the part of certain industries to conserve the health and limbs of their working forces. Prior to that date many concerns had their company surgeons, but the chief duties of these doctors was to anoint the bruises, tie up the cuts and splint the breaks—first aid and emergency care vitally important in any health program, but representing only one angle of the great problem of human maintenance.

At that date, a little more than a decade ago, a few industries began to establish well equipped doctors' offices in their plants, manned by broad-visioned physicians who saw in this group practice living human laboratories for their endeavors—human laboratories wherein the physician, assisted by the industrial nurse, the eye specialist, the dentist, the safety and sanitary engineer, could work out the methods of and observe the results of prevention of disease and accidents, supervision of the health of the working force, treatment of minor ailments in the plant office and supervision of treatment of serious illnesses in the homes of the employees and of all forms of sanitation in the plant, even extending his services into the hygiene of the home and the community.

IMPORTANCE OF MEDICAL WORK IN INDUSTRIAL PLANTS

Gradually, during the last ten years, the number of industries developing some type of a human maintenance department in their respective plants has increased. These departments have usually featured or stressed certain angles of the human engineering program—few concerns have developed a comprehensive, rounded system. For example, one industry has stressed welfare work, and because it has a competent social worker in charge, feels that it is meeting excellently this problem of human maintenance; another has stressed the "safety first" work, and depends almost entirely on its safety engineer to reduce human waste and he in turn can scarcely see how anything but accidents could cause human waste in industry; other industries have stressed the "industrial relations department," usually headed by the employment manager, and he too frequently cannot see the importance of the medical work as a definite part of the industrial relations or curtails the expense of the medical department in order to stress some other angle of his problem—the lay mind cannot grasp the importance of health supervision, early diagnosis or expensive emergency care to prevent more expensive prolonged illness and disability.

On the other hand, too many industries have stressed the medical work and have neglected the other angles of human maintenance—sociological work, employment, safety and sanitation. Again, many of these concerns have fooled themselves or have been fooled into thinking they have a medical service when they employ a cheap doctor for a few hours a day and one or two visiting nurses, and carry on a medical service which is a mere mechanical routine, a farce, a service in name only. The doctor who is only using his industrial practice as a "pot boiler" is not usually interested in the great problem of reducing human waste in that industry.

Of the 2,200 physicians, good, bad and indifferent, engaged in some form of industrial health service in the United States, 500 have affiliated themselves with the American Association of Industrial Physicians and Surgeons. This organization stands for the best possible medical service, preventive and curative, which can be rendered to the working forces of industry. Of this latter number it is conservative to estimate that at least seventy-five are serving great industries which have whole-heartedly adopted every method advocated to conserve the human forces in their employ. From their experiences abundant data have been accumulated to prove our charge of excessive human waste in

industry; likewise to prove the remedial measures adopted are sound and effective.

There is a strong appeal to human sympathy in this subject. As Americans we thoroughly believe in the principle that all men are created equal. We are gradually adding a supplementary principle—namely, are created equal and must have equal opportunity to survive, re-create and live in peace and contentment. However, with this human appeal in the background, I intend to emphasize solely the sound economic principles, the increased efficiency, the saving in labor turnover, the accrued profits to the management and to the workers, the conserving of the nation's human resources which inevitably follow the elimination of human waste in industry.

The last census shows that approximately 42,000,000 persons compose the great industrial army of this country. Figures gathered by the U. S. Commission on Industrial Relations in the years 1913 to 1915 show an average loss of nine days per year on account of illness to the American wage-earner. Figures collected from a great many industries having good, fair or indifferent systems of medical supervision of their working forces show an average of four to seven days per employee lost annually due to sickness. Thus it is evident that even an average type of health supervision will cause a reduction of at least three days per employee in the annual morbidity rate. The cost of the medical service, including many other functions besides those of health supervision, did not exceed an average of \$2.25 per employee per year in ninety-nine industries surveyed by Magnus Alexander.

ECONOMIC LOSS DUE TO SICKNESS

Reducing industrial waste due to sickness by a plan of medical supervision of the entire wage-earning force of the country would result in the following saving in dollars and cents to industry, to the individual and therefore to the community:

42,000,000 workers, losing nine days per year, at an average wage loss of \$3 per day ($42,000,000 \times \27).....	\$1,134,000,000
Reduction of three days per year by medical supervision leaves six days' annual loss, or $42,000,000 \times \$18$	756,000,000
Saving in lost wages to employees.....	\$378,000,000
Cost of medical services necessary to accomplish this, as well as many other forms of savings ($42,000,000 \times \$2.25$).....	94,500,000
In normal times we may assume that the loss in production or in the efficiency of the entire working force equals at least the amount paid in wages, therefore reduction of sickness would save to industry and to workers.....	283,500,000

ECONOMIC LOSS FROM ACCIDENTAL INJURY

Quoting from Dr. Eugene Fisk, we gain another viewpoint on the monetary loss resulting from accidents in industry:

If, as Mock estimates, 200,000 people are permanently disabled by industrial accidents annually, and if we assume that \$35 is the average cost of replacement, this means a direct waste in turnover alone of.....	\$7,000,000
Add to this for those disabled four weeks or more ($875,000 \times \$35$).....	30,625,000
Add for those killed ($28,000 \times \$35$).....	980,000
Increased production costs due to industrial accidents	\$38,605,000

At least 75 per cent of the accident rate is preventable.

Even greater reduction has been made in some plants by safety measures and education. The economic value of these lives on the lowest basis of computation is \$8,000 each and the saving of 20,000 of them (75 per cent) would mean an economic gain of \$160,000,000.

Accidents cripple the efficiency of the working force. Trained employees who are injured must be replaced by new, often inexperienced, workers. It is hard to estimate the loss to industry by this form of forced labor turnover.

ACCIDENT PREVENTION IS CHEAPER THAN PAYING COMPENSATION

Injured employees, non-producers now, cost industry a terrific toll in compensation. In Pennsylvania the gross total of workmen's compensations awarded and paid for fatal and disability cases during two and a half years, Jan. 1, 1916, to July 1, 1918, amounted to \$16,917,000—the amount actually paid to 577,053 injured workers or their families. A cheap price surely, for of this number 3,789 lost either arms, legs, hands, fingers or toes; 1,157 lost one eye; 29 were totally blinded and 7,575 were killed outright. It is difficult to estimate the cost to the industries or to the injured employees (or to the doctors and hospitals often forced to give free care) for the medical and surgical services to these cases.

Figures from many states having compensation laws would indicate that considerably more than \$100,000,000 annually is disbursed in payment of compensation claims to injured workmen throughout the United States. One-half this sum spent by the states in an intelligent accident prevention program would reduce accidents 75 per cent and the amount paid in compensation at least three-fourths. Prevention is cheaper than paying compensation. Compare these two items:

No accident prevention, cost of compensation.....	\$100,000,000
State accident prevention programs, cost.....	\$50,000,000
Cost of compensation for reduced number of accidents.....	\$25,000,000
	<u>\$75,000,000</u>

Here is one common meeting ground for engineers and doctors for the elimination of one of the most appalling examples of wastage in industry.

ECONOMIC LOSS FROM PREVENTABLE DISEASES

Statistics innumerable can be furnished to prove the economic loss from preventable diseases and accidents in industry. But statistics are not as convincing as actual examples of a few methods of preventing human waste.

Engineers can readily understand the importance of examining one thousand intricate, expensive machines which the management of the industry had decided to install. Naturally, this examination would be made before setting up and using the machines, especially if certain damaged parts in the mechanism might cause an explosion which would damage, perhaps irrevocably, some of the other machines. Why not, then, the same solicitous care of the human machine?

When I was making a plea for certain preventive measures which would reduce the number of accidents to our soldiers from industrial causes during the recent war, an old medical army Colonel said to me: "The soldier is the cheapest commodity we have in this great war machine. We expect them to get injured, wounded and killed." He was a small-caliber, narrow-minded

officer, of course. The majority of those in authority saw the value of prevention, realized that the fighting man was the most expensive commodity in the army. The idea of prevention was thoroughly sold to this great industry organized for the purpose of war.

Today, and more true of the past, too many employers and captains of industry have looked upon the worker, the soldier in the industrial army, as the cheapest commodity in his institution—a machine to be used to the utmost and when premature age, sickness or injury overtook it, to be scrapped without further thought. The idea of the expensiveness of this machine and the economy of conserving its usefulness by preventing these misfortunes must be as thoroughly sold to industry as it was to the army.

ECONOMIC LOSS DUE TO UNINTELLIGENT HIRING OF APPLICANTS FOR WORK

The old system of hiring and placing a man on a job and the system still in vogue in many industries was to have the foreman or the employment manager interview the applicant, ascertain his occupational qualifications and then assign him to the job. No thought was given as to whether the man had a bad heart or high blood pressure or an incipient kidney disease when he was assigned to the heavy work of trucking, running a roller machine or running up a ladder fifty or a hundred times a day. Yet this heavy work, incompatible with his damaged physical machine, was responsible for his premature breakdown and mayhap his death. The expense of hiring that man and breaking him in to a job for which he was physically unfit was a dead loss to the industry. Nevertheless he was replaced by the same stupid, blind method of hiring. No thought was given as to whether the man employed had tuberculosis. He had, but he was placed at the job of packing in a poorly ventilated room, in close proximity to a hundred fellow employees. The dust from the packing paper made his disease grow rapidly worse. His coughing and occasional spitting infected three of the men working near him. Just as he was becoming a good packer he was forced to quit. Fear of losing his job and placing his family in want had kept him at work on the days when he should have been home in bed. When he finally gave up the fight his disease was so advanced it was incurable. The three other men, with gradually decreasing efficiency, continued to work until the foreman said:

"What's the matter with you men? You used to be good packers, but now you're no good a 'tall. Get out! You're fired!"

Four men thrown on the scrap heap! Four families a drain on the community because of the unintelligent system of hiring and firing so prevalent in industry! In these same industries expensive intricate machines are very carefully examined by engineers.

Annually throughout the land thousands of such cases of organic disease, kidney trouble, tuberculosis, syphilis, mental and nervous disorders and other incipient disease conditions are being blindly employed, permanently damaged, menaces to fellow employees, and prematurely scrapped as the derelicts of industry. Here is another field where experience has proved that wastage in industry can be eliminated.

EXAMINATION OF APPLICANTS FOR WORK

In 1912 the routine medical examination of applicants for work before they were placed on the job became

a definite function in a few large industries. Later, in 1914, other industries took up this system in order to protect themselves against employees with deformities, hernias, one eye blindness, etc.—conditions which might make the concern responsible for compensation, as in that year employees' compensation acts were passed in a few states. In some industries there were selfish reasons behind the adoption of this method, but among the pioneers in this field humanitarian reasons and sound, scientific business principles prompted the action.

The examination of applicants for work should be for the sole purpose of discovering:

First, those applicants who have some condition in their bodies which makes their presence in the plant dangerous for themselves, for others or for property.

Second, those applicants who have physical or mental defects not entirely unfitting them for employment, but which require careful selection of work in order to preserve their health and make them efficient workers.

Carefully conducted physical examinations will show between 2 and 3 per cent of all applicants totally unfit to work because of conditions enumerated in the first class. Approximately 25 per cent of the applicants will have some diseased condition which can be corrected or which requires the selection of his work as explained in the second class.

Scientific placement, therefore, in order to reduce this form of human wastage in industry, necessitates close co-operation between the physician and the employment manager. The first learns the physical qualifications of the applicant, the latter his occupational qualifications. Scientific placement results according to the following formula:

Physical Qualification

+ Occupational Qualification

= Job

ECONOMIC ADVANTAGES OF MEDICAL EXAMINATION
OF APPLICANTS FOR WORK

The number of applicants who have contagious diseases is not great, but even one case of diphtheria or scarlet fever thrown in among the old working force becomes a potential factor for great havoc, a destroyer of efficiency and an added loss to industry. In one year the writer and his assistants examined 8,000 applicants for work and found 170 cases of contagious diseases, all of whom were rejected permanently or temporarily, as follows:

Cases		Cases	
Tuberculosis.....	102	Mumps.....	6
Syphilis (active).....	10	Streptococcic sore throat.....	18
Gonorrhea.....	16	Smallpox.....	1
Diphtheria.....	8	Trachoma.....	1
Scarlet fever.....	2		
Measles.....	6	Total.....	170

It is self-evident that the health of employees in this industry was greatly protected by preventing these applicants from going to work. The financial saving to the concern by preventing at least five possible epidemics among their working force cannot be estimated.

Four years ago I obtained figures from ten large industries having a total working force of 102,400, which conducted careful medical examinations of applicants for work. The profits to these ten employers

from this system amounted to \$288,000 in one year after paying for their entire medical and nursing services, including all the other functions of the medical departments. Details of these statistics can be found on page 88 of Mock's "Industrial Medicine and Surgery."

HEALTH SUPERVISION OF WORKING FORCE

It is customary for engineers periodically to inspect and examine the plant machinery in order to discover early the signs of wear and tear and when necessary to repair in order to preserve its working span and effective operation.

In a nutshell, that is the purpose of the physician in industry—the human engineer. Not only must the portals of the plant be guarded against unsafe applicants for work but the old working force must be constantly supervised to guard against contagion and epidemics among its members; to discover the incipient diseases early before their advance has robbed the concern of competent, trained workers; to see that the sanitary conditions outside in the community, inside in the plant, and among the employees are such as to conserve health, contribute to their contentment and by all of these add to or maintain their efficiency.

Periodical physical examination, or the examination whenever otherwise indicated, of the old employees is the best method and only scientific means provided for a thorough supervision of health. If these examinations are slipshod or merely routine, devoid of all personal interest in each individual case, very little value accrues to either employee or employer. But if medical talent is employed in whom the managers and foremen have confidence and if every laboratory and other facility is given to examine the workers thoroughly, then great value accrues to the management, to employees and to the community. Such a medical department becomes a veritable community health center and has untold influence over the health of the families of the workers. Without attempting to give home medical service to the families, many opportunities are presented for the visiting nurse or the doctor to relieve illness in some member and thereby relieve worry and increase the efficiency of the wage-earner. After an employee has been thoroughly examined in the doctor's office at the plant, he insists on a thorough examination of some member of his family when that one is forced to consult the family doctor. Thus even the caliber of the outside physician is improved. Not only does an efficient medical department decrease industrial waste but its influence and ramifications decrease human waste in the community itself—preserving to each industry a healthier, more loyal future generation of wage-earners.

WORK FOR DENTISTS AND EYE SPECIALISTS IN
CONSERVING AND RECLAIMING EMPLOYEES

Dental departments in industry have become established units of the medical system in at least fifteen concerns. They are absolutely vital in discovering the diseased conditions about teeth, especially those conditions which insidiously lower the vitality of the worker and often are responsible for the absenteeism which is thought to be due to some other disease. No system of health supervision is complete that does not include dental examinations and some arrangement whereby remedial measures can be placed within the financial reach of each wage-earner.

The eye specialist has become invaluable in the program of conserving and reclaiming employees. In various industries from 35 to 56 per cent of the employees were found with defective vision uncorrected by glasses. While thus far I have found no method of computing the increased output of these workers after they were fitted with glasses, yet the testimony of many managers and foremen indicates that practically all of them have become more efficient and steadier on the job. The good eye specialist can increase the efficiency in whole departments by suggesting and supervising changes in illumination. He can help enforce the protective measures installed for the prevention of eye injuries.

WASTE FROM MINOR INJURIES

Besides the usual measures incorporated in "safety first" and accident prevention programs, the physician in industry can eliminate many sources of waste the result of accidents. Minor injuries are said by accident casualty companies to cause considerably over 50 per cent of the disability cases. This is due to the fact that most of these slight injuries are neglected until some complication, usually an infection, forces the worker to consult a doctor. Forcing every case, no matter how slight the injury, to see the doctor in the plant at once and the use of tincture of iodine on every scratch, pin prick, nail wound or other lacerating wound have resulted in a great decrease in infections and in minor injury disability. Sherman reports only 0.1 per cent of all accident cases in the Carnegie steel mills become infected. In my experience I found that 78 per cent of all accident cases reporting to the doctors' office in 1909 were infected. By instituting the rules about reporting and using tincture of iodine at once there was an immediate reduction of 28 per cent in the number of infected cases. This decrease continued until only 7 per cent of all cases showed the least sign of infection and only 0.2 per cent lost time on account of infections.

Immediate care of every injured employee, treating each case as serious from the moment of injury and the use of the best hospital facilities will reduce the lost time on account of accident disability and will reduce materially the number of cases of permanent disability and permanent deformity. Here again careful physical examinations of the employees will often reveal potential causes in the human machine for accidents either to themselves or to fellow employees.

Real co-operation must be developed between safety engineers and physicians in industry to obtain 100 per cent value from any accident prevention program.

CASUALTIES IN THE INDUSTRIAL FIELD

It is conservative to estimate that the casualty lists from the industrial army in one year in this country are at least three times greater than the casualty lists sustained by our army in the World War during the bloodiest year of fighting. Millions have been spent by the Federal Government for the reclamation of our disabled soldiers, and a great many more millions must be spent before the nation's promise of rehabilitation to the disabled is even properly administered, let alone realized. These efforts to rehabilitate the soldier have awakened the nation's conscience to the importance of rehabilitating or reclaiming the disabled from industry.

From the industrial field alone, consulting statistics

furnished by the Department of Labor in 1917, one finds that annually 875,000 men and women are disabled for more than four weeks as the result of accidents sustained in industry; that annually 76,000 suffer loss of members, and at least 200,000 are otherwise permanently disabled by industrial accidents, that each year 28,000 are killed as a result of industrial accidents. Conclusions drawn, after the investigations of many different authorities, indicate that at least 250,000 wage-earners are lost annually in our country due to occupational diseases.

RECLAMATION OF THE DISABLED

With the exception of some of our large industries and a few far-visioned insurance companies, practically no organized effort has ever been made for the reclamation of these hundreds of thousands of permanently disabled men and women. A few industries salvage their disabled, making them efficient and independent, others give injured employees easy jobs where they can make a living, but the very softness of the job robs them of all incentive, and the bitterness engendered by dying ambition adds to their incompetency, forcing them on and on to the scrap heap. The majority of concerns settle with and then dismiss their injured workmen for whom they are legally responsible; the disabled for whom they are morally responsible are scrapped without a settlement. These men, trained for certain occupations, who meet with permanent handicaps, are the waste products of our industrial life. Too often when the handicapped individual is employed he is ineffective, because the job was chosen for him without considering his physical fitness for it. Many of these disabled men for whom no employer feels responsible drift from one job to another, constantly dropping to a lower level, until finally they relinquish all effort to work. These become the loafers, the beggars on the corner, the shoestring merchants on the street, the poor, physically handicapped and mentally debased flotsam and jetsam of our civilization. The great majority of these handicapped persons cry out not for charity, not for the easy job, but for a chance to make good and to advance. The testimony from a great many employers who have employed handicapped individuals indicates that they are efficient, capable and will often stick by the job better than the able-bodied man.

NEEDED FEDERAL LAWS FOR VOCATIONAL TRAINING OF THE HANDICAPPED FROM INDUSTRIAL ACCIDENTS

I prophesy that within the next ten years every state in the Union now having employees' compensation laws will likewise enact laws and establish machinery providing for the rehabilitation of these permanently handicapped individuals. Already Rhode Island, Pennsylvania, California and Illinois have adopted rehabilitation laws providing for more or less limited efforts along this line. The Federal Government has enacted the Smith-Sears bill, which deals with the vocational training of the handicapped from industrial accidents by co-operating with state efforts. All of this is more or less piecemeal legislation, especially the latter law, as vocational training constitutes only about 10 per cent of the problem. It is placing the cart before the horse, but nevertheless even this law indicates an awakened conscience on the part of the lawmakers.

In an effort to work out a practical solution of the entire problem of rehabilitating the physically handi-

capped both from accident and disease, an organization has been perfected in Chicago during the last year, composed of leaders in industry and education, a large group of women representing the various social agencies, and a medical board of representative physicians and surgeons of the city. This is known as the Service League for the Handicapped. It has an executive committee made up of fifteen of the most influential business men, with medicine, education and safety engineering also represented. Its board of management is composed of delegates from almost every agency in the city dealing with some phase of the problem of the handicapped. Through its connections with the public school system, the universities and many industries and through its own workshops which are now established, practical re-education of the handicapped for lucrative employment is made possible. It maintains an employment bureau which directly or through the state and private employment agencies is successfully replacing many handicapped individuals in industry. This Service League stands as a halfway house between hospital, where the reconstructive surgery is done, and the future employment of the disabled, where his rehabilitation will be completed.

No plan for eliminating human waste in industry is complete that does not include this salvaging process—a process which aims to reclaim those who become disabled in spite of all the great preventive measures which are being advocated or have been installed. Keep in mind human salvage as well as the elimination of human waste.

COMMUNITY CO-OPERATION

The burden of the care of the sick and injured from industry must fall on either the individual, industry or organized charities, when neither the first nor the second is responsible financially for that care. The succor of the individual and of his family by the charities is humiliating and after all is a tax, as the majority of the community must contribute to charities. Frequently the burden is too great for the individual endeavoring to carry it alone, and as a result insufficient or improper medical, surgical and hospital care is obtained, resulting in prolonged disability and often complete loss of the wage-earner, either being a very material loss to industry. Many large industrial concerns and groups of smaller industries have proved their ability to organize efficient medical departments. These, or insurance companies representing them, assume the cost of furnishing adequate medical and hospital care and the additional cost of paying compensation sufficient for the family to maintain its integrity and its natural position in society, and add the expense of such protective measures to the cost of production. Even this burden is a tax on society, for the consumer must ultimately pay, yet the benefits in return to all society offsets this tax a thousand-fold.

The alternative method is for the state to impose a sufficient tax to meet these problems of prevention, treatment and reclamation of the disabled wage-earners. Personally, I do not believe many states are equipped to handle the problem as efficiently as are individual industries or groups of smaller industries. The tax would undoubtedly be much greater than if the burden was carried by a small addition to the cost of production.

The physician in industry more than any one else

has come to realize that the questions of health in industry, as well as many of the other industrial relations problems, deal not only with the individual employee, but rather with the employee and his family.

COMMUNITY HEALTH CENTERS THE SOLUTION FOR ELIMINATING HUMAN WASTE

When considering the preventive and the remedial measures as a means of eliminating human waste in industry, all methods developed must be applied to the community as a whole. The organization of community health centers to which industries will contribute for the adequate supervision and care of their working forces will undoubtedly be the ultimate solution of this great economic and social problem. Such centers would enable the development of a co-operative plan between community and the industries of that community for the purpose of eliminating human waste. It would safeguard for industry the expensive human machine while employed in the plant, while on the streets and while at home. It would guarantee a better system of preventive medicine, better medical and surgical care, better hospital provisions and would prolong the work span and life span of every individual.

Laying aside the old doctrine of "the survival of the fittest," we seem to be entering upon a new era—the conservation of man, the noblest work of God.

Chicago, Ill.

Loss in Production Due to Ill Health

A report on national vitality prepared in 1909 for the National Conservation Commission, appointed by President Roosevelt, estimated that there were then about 3,000,000 persons seriously ill at all times in the United States. This meant an average annual loss per person of thirteen days owing to illness. It was estimated that 42 per cent of this illness was preventable, and that such prevention would extend the average life by over fifteen years.

The committee appointed by the Federated American Engineering Societies to study the elimination of waste in industry states in the summary of its report (July, 1921) that since the 1909 report was issued an evident reduction in illness has been accomplished, so that today an estimate of between eight and nine days is probably near the fact.

Tuberculosis is the most important disease among industrial workers, two or three deaths per 1,000 per annum occurring at the working ages. It is estimated that 3 per cent of the wage earners, or about 1,250,000 lives, are affected. The economic loss from tuberculosis death rate as affecting the working population is \$500,000,000 annually.

Pneumonia, influenza and typhoid fever are the most important communicable diseases among adults. Influenza and pneumonia, in non-epidemic years, take about 35,000 lives in the working ages and account for at least 350,000 cases of illness. Typhoid fills close to 150,000 sick beds annually and takes 15,000 lives, mostly in the working ages.

In a large industrial area hookworm infection was present among at least 5 per cent of the laboring population.

Malaria is so seldom a direct cause of death that it is difficult to estimate its extent and influence, but it is responsible for much sub-standard health, and probably affects 1,500,000 persons annually, covering 27,000,000 days' absence.

Waste Due to Poor Engineering and Management

Sound Engineering Practice and Competent Management Are the Most Effective Methods of Eliminating Waste—Accurate Cost Records of What Has Been Done Should Make Possible the Prediction of Improved Results

BY DEXTER S. KIMBALL

Dean of College of Engineering, Cornell University

FOR a number of years certain industrial engineers have been advocating a more careful consideration of industrial wastes as a part of more efficient management. Received rather complacently at first by managers, this idea has now grown to be one of the most prominent and also one of the most promising fields of industrial betterment. The appointment by Mr. Hoover, as president of the Federated American Engineering Societies, of a special Committee on the Elimination of Industrial Waste has done much to arouse still greater interest in this matter, and the forthcoming report of this committee is expectantly awaited. A very interesting feature of this report is a recommendation that uniform cost systems be established in all industries as a means of evaluating and checking industrial waste. This is a perfectly logical conclusion. Costs, if properly considered, are financial statements of what has occurred. They provide a basis for comparison of results and also for predicting future policies.

WHAT IS INDUSTRIAL WASTE?

Like all seemingly new industrial problems that receive such publicity, the elimination of industrial waste will be much discussed, no doubt, and possibly some extravagant claims will be made concerning it. Some confusion seems to exist also in the minds of some of those who have discussed the matter as to just what is definable as industrial waste, and before going further it may be well to inquire just what the term really involves; for waste can be prevented only when it is understood.

WASTE OF MATERIALS

Waste of materials is usually quite tangible and, hence, usually preventable. If a workman uses more material of any kind than is actually necessary for a given operation, waste results; or he may waste material through spoiling the work on which he is employed. Material may be wasted through inefficient or inadequate equipment, as in the case of a boiler room where coal is not properly burned. Also great material wastes often occur because of careless handling and storing of material, through actual loss of material and through preventable depreciation.

LABOR WASTES

Labor wastes are not always so evident. If a man expends more time upon a piece of work than is necessary, waste results; or if he is paid for time during which he does not produce, money is wasted. Time may also be wasted through the use of inefficient equipment or poor methods. The loss through these last two resources are often very great and often not appreciated.

It does not follow, however, that waste results when a man works eight hours when he could work ten. Perhaps eight hours is as long as he should work. Nor can it be said that there is a waste because a plant operates only eight hours out of the twenty-four. In some industries it is necessary to operate continuously to produce economically, but the term "waste" must be applied with care to the period during which a plant operates. Again, it does not follow that a workman wastes time because he is not working every minute of the time for which he is paid. He usually can produce more product if he is given definite rest periods. This is a fact proved by actual experiment.

IDLE EQUIPMENT

Losses and wastes due to idle equipment are also somewhat elusive. Clearly there is a waste of time and of interest on investment when a machine stands idle though there is work for it but, because of poor planning, the work is not ready. It does not follow, however, that all such idle time of equipment is chargeable as waste. Quite frequently, and particularly with large equipment, it is not possible to keep all machines in operation; yet these machines may be absolutely indispensable to the life of the business. The interest on investment during idle periods is a just charge against production, and should be so recognized and cared for in the costs, and if this is done, such interest cannot be classified as a waste. It may occur that the line of work that demands machinery and equipment which operate only occasionally does not pay a profit, and in such case the entire procedure may well be called a waste.

ALL WASTES NOT PREVENTABLE

It should be remembered also that all wastes are not preventable. Wastes of material and time through carelessness or bad management can usually be reduced to small amounts, if not entirely eliminated. But buildings and other property, even when kept in good repair, waste away slowly and in course of time must be renewed. Unless provision other than repairs is made for such wasting away the capital invested will in time be depleted. And again it may not pay in some instances absolutely to prevent all waste. Thus the wasting losses through radiation from a steam pipe may be reduced to a small amount by covering the pipe with a thick layer of non-conducting material. The cost of covering the pipe with a layer of such material, thick enough to prevent any radiation whatsoever, would in all probability be greater than would be warranted by the saving made over the case where a moderately thick layer was used.

The foregoing brief consideration of industrial wastes should make it clear that wastes cannot in general be detected by casual observation. In many cases, of course, the waste may be so apparent as to be so detected, but many large wastes are difficult to detect and difficult to prevent. And it will be obvious that unless the character of the waste is known it is most difficult to prescribe remedies for it. This is particularly true of wastes due to careless or inefficient management and organization. And even when the character of the waste is obvious it is not often easy to evaluate by observation the amount of the loss occasioned.

PREVALENCE OF LACK OF KNOWLEDGE

Most industrial waste and loss are due to lack of knowledge, and many data are available which indicate that the majority of business failures are due to incompetence; particularly that form of incompetence that comes from lack of accurate knowledge of some part of the business.

Bradstreet's reports for 1911 and 1921 give some very interesting data on the matter which indicate that four-fifths of the business failures in this country are due to incompetence of one kind or another on the part of those that fail. And no doubt much of the incompetence comes from lack of knowledge regarding some phase of the business, and particularly regarding wastes and wasting losses.

One of the most effective methods of evaluating wastes is through the cost system, and no cost system is worth considering that cannot be used to evaluate any given waste. The character of wasting losses naturally varies with the character of the business, though some wastes, such as depreciation, are common to practically all industries. A cost system may or may not reveal the character of wasting losses in a given industry, but cost-finding methods can always be employed to evaluate any loss once its character is determined. Every careful manager should therefore study carefully the wasting losses peculiar to his business, evaluate them by financial standards through his cost system and proceed to eliminate, as far as possible, those that are important enough to be considered. A few particular cases may make these points clearer.

LOST TIME

In all industries there is more or less lost time. Machinery breaks down or lights are temporarily extinguished, thus causing temporary idleness for which pay is not deducted; or workmen are idle because work or tool is not at hand. In many cost systems such lost time is charged directly to some productive job order number and thus buried in the cost. If the amount of lost time is small, this may be all right, but a better procedure is to carry all such lost time to a separate account and distribute this account in the expense or overload. Such an account becomes a measure of efficiency in management and will show not only the amount of such losses, but can be made to show the responsibility for such losses. Usually the most of these losses are due to poor planning of the work on the part of those in charge or to inefficient care of equipment and lack of foresight in keeping important machinery in proper repair. Such an account will not, however, reveal wasted time due to "loafing" on the part of the workers themselves.

Lost time in its relations to the payroll may be very important in itself, and if the idleness involves high-priced machinery, this factor may be of much greater importance, since then there is loss of interest on invested capital. This type of loss has several aspects. First, there may be loss of time in operating machines well fitted for the work in hand for the reasons already enumerated. Again there may be waste of time because of work performed on equipment not well suited for the purpose. And, lastly, there may be machines or processes in the plant that are used to such a small degree as to be a source of loss instead of profit. Occasionally, of course, as has been stated, machines and processes may have to be retained, though used only occasionally because of some peculiarity of the business. But an examination of many plants, particularly old plants, will show equipment and apparatus that are occupying valuable space and yet yielding so small a return as to constitute a loss. The case is analagous to the farmer who keeps an unproductive hen or cow, and the remedy is the same in both cases—through cost-finding methods. A record of all idle time for all equipment and a comparison of this idle time with the earnings of machines showing a large amount of idleness will often result in changes in equipment that will cut off much wasted time. Information of this kind can be easily obtained through ordinary cost-finding methods.

STOREKEEPER CUTS DOWN WASTE OF MATERIAL

Good cost methods are always useful in preventing wasteful use of material. It is still customary in many shops to permit workmen to draw material at will from the stores. It is true, of course, that in small shops, particularly where the material is of no personal value, it may not pay to employ a storekeeper and workmen may be permitted to help themselves from bins and racks. Such cases are rare, however, and usually it pays to have a storekeeper. It is a small enterprise indeed where a storekeeper will not save his wages. It is universal experience that workmen, when allowed to draw material at will for fabrication or general supplies, become careless and wasteful not only as to the quantity drawn but also as to its economical use. Loose storeroom methods also are likely to lead to dishonesty and petty pilfering on the part of employees.

Under a good cost system the storeroom is closed to all but the storekeeper and his assistant, and no material may be issued without a proper order any more than money can be obtained at a bank without a check. Material is just as valuable as cash in the safe and should be so treated. Under a good cost system all material drawn is charged to some production or expense order and properly accounted for. Aside from the actual savings made by properly regulating the withdrawal of material from stores, such regulations serve to accentuate constantly the value of material and assist in forming habits of thrift in all concerned.

Material wastes due to overissuing or careless drawing of material can be kept in check by good storeroom and cost methods. There is usually, however, a considerable amount of unavoidable material waste due to cutting, sawing and other fabrication processes. In the case of copper and similar valuable material, these wastes may be considerable, and even with

cheaper material, as sheet steel, when large quantities are used the value of the scrap may be great. If the waste is in such form that it may be returned to stores and used again for other purposes, the cost system should be such as will credit the original job with such salvage value as may be fair to it.

DEPRECIATION OF MATERIAL

Another common source of material waste is depreciation of stores materials due either to poor storing or to obsolescence. The remedy for the first cause is obvious, but the second is not always so easy to recognize or to obviate. Obsolete unworked material usually comes from careless ordering or changes in design, and many kinds of stored material depreciate rapidly, particularly if it is at all special in character. Finished product often depreciates through obsolescence due to changes in market conditions. Cost-finding methods, as usually operated, will not reveal such losses, but a close study of the inventory will make such losses apparent. The engineering or designing department can do much to lessen these losses by consulting the inventory when designing new apparatus so as to use material on hand where possible.

Depreciation of buildings and equipment through wear and tear, action of the elements, obsolescence, etc., are, however, wasting losses that can be and should be clearly shown and compensated for in the cost system. The method so much in use of charging off depreciation as a lump sum or percentage annually is no longer considered good business accounting. Losses of this kind are a legitimate part of costs and should be included so far as possible in the charges made for each machine and process as the work passes through them. In all good cost systems systematic provision is made for including depreciation in the regular cost of production. In this way, and in this way only, can intelligent compensation be made for such losses.

SPOILED WORK

An excellent example of the value of a cost system in evaluating wastes is in connection with spoiled work. It is still common practice to charge spoiled work to the job order number under which it has been performed. If the spoiled part is one of a large number, this procedure may often be defended. But more modern practice is to carry the cost of spoiled work to a special account that is discharged into the expense or burden as in the case of lost time. No matter what disposition is finally made of such an account, the practice is good in that such an account gives the manager an idea of the magnitude of this waste and the information necessary to correct the loss if it is serious. Spoiled work, like lost time, is a measure of the efficiency of management. Some managers go so far as to keep a record of the breakage of small tools and apparatus by individuals partly as a means of evaluating the loss and partly as a psychological check on carelessness.

Other specific examples could be given of the relation between cost finding and wastes, but the foregoing should be sufficient to indicate these relations. Obviously these wastes may be due to incompetence or carelessness on the part of either employer or employee, or both. Wastes due to poor management are not always easy to detect or evaluate. Thus a rearrangement of machinery or changes in administrative methods may not be reflected in the costs as

clearly as in the examples cited. In general, however, all such changes must eventually affect costs in some way or another, and in fact the result of any and all charges can be evaluated accurately only by a study of comparative costs.

PLANNING IN ADVANCE

The foregoing discussion has assumed that costs are considered only as a record of what has been already accomplished, and this is the usual conception of cost-finding methods. A more modern view is to consider costs as results to be attained, planning deliberately to arrange machinery, personnel and wages in advance so as to produce the desired result; and advanced thought in management is moving steadily in this direction. Careful consideration will make it clear that wastes such as lost time, material wastes, losses due to broken machinery, etc., can be greatly lessened by careful planning and foresight. The planning department, which aims to accomplish these results, is now a common feature of modern plants and many enterprises that produce complex and refined products are now running on schedules prepared in advance that cover the entire range of operations in which all time elements and all ways and means are predicted in advance of production. Undoubtedly the remedy for much industrial waste lies in managerial changes of this kind.

It will be clear, for instance, that if the amount and quality of material for a given piece of work are determined in advance and provision is made so that only this amount of material can be drawn for this purpose, much of the material waste now so common in many plants would disappear. The case of plant supplies is equally clear. Every manager knows that when workmen are free to help themselves freely to oil, brooms and similar material the tendency to waste the supplies is almost irresistible. Many careful managers now determine in advance just what the needs of each man may be and arrange a budget for all supplies, thus preventing unnecessary waste. Departmental expenses can be budgeted in a similar manner. It will be noted that aside from the actual savings thus attained, such methods tend to stabilize the costs, making prediction much more definite.

FUNCTION OF THE MODERN COST SYSTEM

It should be remembered, however, that budgeting and predicting of costs in advance can be accomplished only after accurate data are available. The power to predict in advance rests generally upon a knowledge of what has already been accomplished. A modern cost system, therefore, should perform two functions—namely, recording what has been done and making possible the predicting of what should be done. It does not follow because a piece of work has cost a given amount that it cannot be performed for less than that amount. One of the greatest criticisms of modern cost accounting methods is that usually they tell simply what has occurred and do not show what should occur. If the manager can have placed before him the statement of work accomplished and also a statement of the wasting losses and other defects in his organization and methods, it is usually not a difficult task to make such changes as will make prediction of results and the attainment of the same a hopeful possibility.

Ithaca, N. Y.

The Educational Waste in Industry

BY HOLLIS GODFREY

President, Drexel Institute, and Chairman, Council of Management Education.

IF IT be true that 50 per cent of the waste today in industry is due to management, the fault lies in industry and the college. That 50 per cent may be termed the educational waste, as it never could exist had there been proper co-operation between the colleges and industry in the past. The energy of education is the one force which is directed to stop management waste. Education is the salvation of industry.

COLLEGE MAN, PROPERLY TRAINED, NEEDED

Go to the captain of industry today and ask him what type of man he needs in his management group. He will tell you the college man when properly trained. He will tell you that the average college man is not properly trained and that for two years he is virtually useless to the organization; he will tell you that it costs at least \$2,500 to train that man before he can accept a position of responsibility in the company. But he will emphasize the fact that the man he takes into the corporation when a fresh graduate from college cannot accept responsibility and that his training has almost been a detriment in so far as industry is concerned.

It has been my good fortune to make a study of industry across the United States and to talk industrial waste and educational waste in industry with more than 275 of the largest employers of men. The average opinion of college men is the same. All agree, however, that the college man holds the key to the situation, that it is his problem upon entering industry to stop the leaks, to increase production, to decrease cost and to stabilize industry. How is he going to do it?

INDUSTRY LOOKS TO THE COLLEGES

In the face of almost universal criticism, industry yet looks to the college for the solution of its problems. Industry, with its keen, practical eye, sees farther than the mere lad who comes to its door to gain a livelihood; industry looks to the future. The great capitalist of today who studies the balance sheets sees that the educational waste in industry must stop, and in stopping that waste the very waste in management is terminated. The captain of industry knows that 12,000 men each year leave the colleges and enroll in industry with no previous training to equip them for life in industry; he knows that it takes two years to train those men in the plant at a cost of \$2,500 each and he knows that forces today are at work to stop these losses. Industry is interested in the project which has for its purpose the training of these thousands in the college, is grappling with the problem of the undergraduate to save the boy years of work and to save industry 24,000 years each year and millions of dollars in money.

A MOVEMENT TO BRING THE COLLEGE AND THE INDUSTRY TOGETHER

I have the honor to be the chairman of the Council of Management Education, which is dedicated to the work of eliminating this frightful waste in industry and the college. No one is to blame for the mistakes of the past, but, thank God, we are seeing light today.

The difficulty has been that industry and the college spoke two languages, two tongues which neither could speak or comprehend. Industry wanted the college to help, the college wanted to help; but both were in the position of a French manufacturer who would do business in America with French measurements and language, both of which the American manufacturer could not understand.

Slowly through the years a movement has been on foot to bring the colleges and industry together. The greatest step was made during the war. We had gathered around us in Washington the leading men of industry and the leaders in the college world. They worked, planned, dreamed together and when the armistice was signed some of these men decided that the great advance should not be lost. A survey of the entire country followed. This was made through the Technology Clubs Associated, and from this body of war workers and growing out of a conference held in Drexel Institute, Philadelphia, in March, 1920, of those most vitally concerned, the Council of Management Education has come.

THE WORK OF THE COUNCIL OF MANAGEMENT EDUCATION

Today the Council is backed by industries having a combined capital of \$23,000,000,000. Sixteen basic industries are in the movement and a number of others desire admittance as soon as the Council can undertake additional work. The colleges of the country, through the American Council of Education, which has appointed a group of educators to co-operate with us, are working in the closest accord. The majority of the colleges have written independently and offered their entire services. The Governors of every State in the Union save four have appointed representatives to act with the Council.

Thus, industry and the colleges are "getting together." It is an earnest effort to form a central body to consider the problems of each for the benefit of each. It is a non-profit-making body of the highest academic standing and its work is for public service alone.

A CLEARING HOUSE BETWEEN THE INDUSTRIES AND THE COLLEGES

As a great clearing house between the industries and colleges of the country it studies the problems of the firm which needs chemists, engineers, men versed in any particular line and, in turn, it studies the problem of the college to supply the men. It is a problem of industrial demand and educational supply. The men in the Council speak the language of the industry and of the college; each holds a major professorship in one of the leading universities and each has had his turn in cold, practical industry. Men of this type alone can take the facts of industry and college and make them available to both.

Eliminate waste—waste in the chemical industry, iron, cotton, rubber—the Council of Management Education has dedicated itself to this task as a service to mankind. I may add that it has been the good fortune of the Council to include several of the nation's greatest chemists in its roll. We earnestly ask the co-operation of all industries and hope the readers of CHEMICAL & METALLURGICAL ENGINEERING will assist the Council in its great task of service.

The Role of Research in Waste Elimination

Encouragement of Fundamental Research in America Is More Urgently Needed Than Stimulation of Industrial Research—Fallacy of Curtailing Research and Disrupting Organization in Times of Industrial Depression—Examples of Waste Eliminated by Research

By HARRISON E. HOWE
National Research Council

FOR the purposes of this discussion waste may be defined as materials, time or labor unnecessarily used in industrial operations and as finished products which fail to measure up to standards set for first quality in any given field. We may also include under waste values delivered in excess of requirements, but we shall not consider the profitable utilization of otherwise waste byproducts of industrial operations, for that subject, while never exhausted, has frequently been presented in convincing style. It is because most people think only of byproduct utilization when research is mentioned in connection with the elimination of waste in industry that there may be some justification for this article.

While the application of the results of research frequently presents a new problem as difficult as the original investigation, it is not to be confused with fundamental research. There are still many productive scientists, especially among the various kinds of engineers, who classify difficult development or control work with true research, and who are a little prone to think that real accomplishment is theirs rather than the theorist's. And yet we all know, if we will but pause to consider, that our work if sound must be based on the laws, principles and theories developed and established through research on real fundamentals usually many years before their practical application.

NEED FOR MORE FUNDAMENTAL RESEARCH

There is far more need to encourage fundamental research in America than to stimulate industrial research, notwithstanding the fact that many industries are not yet founded upon a science. A number of great industrial laboratories have shown their appreciation of this by taking up such work and others have made substantial contributions to educational institutions and organizations striving to encourage such research, that more may be accomplished. President Nichols of Technology in his inaugural address calls attention to the fact that we have about exhausted the store of knowledge which has been hundreds of years in accumulating and that we must have new facts in order to make greater progress. While we may not be in immediate danger, the time may soon come when several lines of industrial development will be hindered awaiting the completion of research just as were the sciences dependent upon optical instruments before Abbe's plea for improved optical glass, without which his dreams could not come true.

FALLACY TO CURTAIL RESEARCH IN HARD TIMES

With this state of affairs, why will industry consent so readily to the curtailment of research when soft times pass? This policy leads to one of our serious industrial wastes. It has been surprising to find how

many firms have made what seems the mistake of breaking up laboratory organizations even to the point of losing men of long terms of service. Such industrial retardation as that through which we are passing offers an excellent opportunity to weed out undesirable or inefficient workers, but it is not the time to dispense with valuable men. As it is, the present really offers to the courageous the chance to build up a strong laboratory organization and the time to engage upon problems which must be put aside in busier times. It is a pleasure to point to those concerns which firmly believe in research as their most potent anchor. These have undertaken research convinced that it will not only enable the elimination of waste to the point where costs will be much lower but that quality will be so improved as to enable the market to be held in the face of poor business and lead customers to discard competitors' wares first when purchases are curtailed. This faith has been justified, and such manufacturers have retained their staffs in the laboratory.

Ideas grow rusty as does machinery. It is not easy to pick up the problem just where it was shelved when the laboratory was closed. Recently a company which had established a research laboratory a year or two ago decided to close it and disband the staff. Something like \$100,000 had been spent and some of the problems were nearing completion. What possibility has that company to realize a return on the money spent? The problems were either unfortunately chosen or the work upon them poorly managed or a blunder has been made in stopping work. Research cannot be profitable unless well managed and adequately supported for sufficient periods of time and unless several well-chosen problems are in hand. Every problem cannot be a winner, and allowance must be made for the disappointing ones.

UNNECESSARY PRODUCTION OF SECONDS

The unnecessary production of seconds is an important industrial waste and usually indicates a lack of proper control of raw materials or of the process. Goods sold as first quality which in use prove to be second quality are even worse. Before materials can be so managed as to give a high percentage of first-quality product, research may be required to determine why reactions go the way they do. The more we know the why of what takes place, the better can we govern the procedure. While we still lose much from unsound castings, just recall the state of the art before research showed the beneficial use of metal scavengers and provided the considerable list of deoxidizers from which the foundry may now choose according to its needs. Some of these materials produce such vigorous reactions as to raise the temperature of the metal, thus serving to bring cold baths to the proper pouring temperature.

Research has not only provided improved pyrometers

but has shown many industries how to use them. It has been found that the relatively few degrees between estimated and real temperature often account for second-grade or useless products. It has been difficult for the research man to convince the others of the importance of a few degrees of heat. The failure to check the accuracy of the pyrometer is an illustration. On one occasion this meant the rejection of 70 per cent or more of a small heat-treated steel part. After trying everything else a research man was called. He checked the pyrometer first, found the error and soon after had the plant on a basis where 95 per cent of the product passed as first grade.

CHECKING AUTOMATIC INSTRUMENTS

In many industries waste has been eliminated by the installation of scientific instruments designed for automatic measurement or control. But instruments wear or get out of order and need occasional inspection. There is the case of a gas company which was operating at a loss. It was a chemical engineer who found that its meters were incorrect, and the simple process of correcting the meter turned a loss of fifteen cents per thousand cubic feet into a profit of as much or more. Recording pyrometers have done much in eliminating waste, for they assist in the standardization of processes in accordance with best practice and enable mismanagement of apparatus to be detected easily. Apparatus for automatically analyzing flue gases and recording the content of carbon dioxide has provided checks on firing-room practice that has saved quantities of fuel. More recently a new type of indicator for high-speed internal combustion engines has been developed in the research laboratory, and by means of this device it is not only possible more accurately to determine the performance of the motor but to obtain more power through an adjustment of timing, etc., precise to a degree not previously attainable. With millions of internal combustion engines in use the elimination of waste accompanying a small increase in efficiency becomes very important. A 30 per cent increase has been attained in several instances with the aid of this indicator.

RESEARCH AIDED TRANSCONTINENTAL TELEPHONE

When it became desirable to talk across our continent there were those who thought the only possibility lay in reconstructing all the telephones then in use and providing them with new transmitting equipment. This would have cost a huge sum and would have entailed extensive waste in discarding otherwise useful parts. Research prevented such waste by devising the audion and the amplifier. These instruments enable masses of energy to be controlled by a few electrons so that sound waves may be strengthened and magnified without changing their characteristics. Energy may thus be brought in to make up for losses and to balance the lines. This is one of the reasons why long-distance telephony is often more satisfactory than local calls and why millions of telephones without change in themselves had their radius of usefulness increased enormously. Research made unnecessary expenditure which would have been many times the cost of this research.

Now we are about to see another step taken in the installation in many of our largest cities of the automatic telephone, heretofore used principally in smaller places. This does involve replacement of plant and equipment to a large extent, but it will be a saving

through better efficiency and reduced cost of operation. Waste often ensues in a plant due to reluctance to replace antiquated equipment when new machinery, etc., has been developed to the point of effecting large savings in time or labor. Indeed, many plants contribute to waste because of poor layout and improper equipment which is used rather than undertake the first cost involved in putting the plant on a sound basis.

RESTORATION OF CRIPPLED INTERNED GERMAN SHIPS

When the German fleet in American waters was crippled by its crews they were under the impression that they had wasted or destroyed a vast amount of property at a time when it was most valuable. For some years research had been devoted to welding—gas, thermit, electric. With many problems still unsolved, the art has made substantial progress and in record time—a tenth that allowed by the wreckers—the ships had been repaired and a waste eliminated.

IMPROVEMENTS IN ELECTROPLATING

Electrodeposition of metals has been a potent factor in waste elimination. Research has shown how electroplating can be used to bring a part up to dimensions or weight and save it from the scrap heap. Examples are common in which electroplating enables a cheap metal to serve in place of a more expensive one. This is not only true where it is a matter of color or finish but where durability is the factor. Recently a method has been perfected whereby a plate for engraving can be so built up as to have a surface harder than steel, and more durable. As one master plate serves for the production of a number of plates for the presses, the possible saving is obvious.

ELIMINATION OF CORROSION

Waste due to corrosion is as extensive as any other, and research is showing the way to its elimination. As a result we now know something of how to remove oxygen from the water in heating systems and plumbing. Where open feed-water heaters are employed most of the oxygen is eliminated and the remainder disappears when the water is caused to flow over steel sheets so placed as to cause the oxygen to combine chemically with the iron of the sheets rather than later with the iron in the pipes. Water so treated has no after-corrosive effect. It has taken time and effort to show that such corrosion is caused by oxygen and not by carbon dioxide or other agents. Zinc plating has been found to be a very efficient base coating to resist many types of corrosion and upon it the desired finish may be built up. The lacquers, the enamels, the acid- and alkali-resisting paints, varnishes, vitreous enamels, glass linings, improved earthenware and fused quartz indicate what has been accomplished in providing weapons against corrosion.

Research has taken another means of defense against this wasteful agency by the preparation of non-corrosive alloys. Some of these have remarkable properties fitting them for unusual service such as substituting for platinum and offering an opportunity to conserve that precious metal. Others of these alloys have been found of greatest use in cutting metals, as for instance stellite, said to have one and a half times the efficiency of tungsten steel.

These alloy steels have so increased the possible productivity of men and machines that to endeavor to operate without them constitutes an industrial waste.

A given machine equipped with ordinary steel tools can be operated three times as fast if tungsten steel cutting edges are used, which means increased productivity for the machine operator as well.

DETERMINING SPECIFICATIONS FOR RAW MATERIALS

Resources are wasted in industry when there is failure to employ industrial research in determining specifications for raw materials. Cost alone is never a safe guide and even well-established brands may change at times. Progressive manufacturers now realize that their service departments are incomplete without research men who co-operate with the users of their product in learning their exact requirements. One manufacturer knew that he must use a peculiar paper in a certain type of cable and was in the habit of buying a costly grade from a reliable source. In time research was employed to find just what it was in a paper that the cable required and the result was a saving of \$9,000 a year on a pre-war cost basis. The tendency to regard cost as the true index of value in a particular case has often led to waste in the purchase of lubricating oils and further waste in their use, since proper lubrication was not always obtained. Lubrication is still a difficult subject, but there are several scientific factors involved in selecting a proper oil and in many cases the laboratory has found less expensive oils more satisfactory for a given purpose. Without research upon the subject suitable oils could not have been produced, and without research upon their use consumers might be subject to much the same practice as were householders who bought their butter of a man who understood the average unadvised purchaser. He displayed butter at three prices. His sales were almost all from the most expensive. All the butter came from the same tub.

RESEARCH ON STRENGTH AND NEW TYPES OF MATERIALS

Waste has been eliminated through researches upon the strength of materials. When no accurate data were available it was necessary to have every member of a structure much oversize to be sure it was strong enough. Engineers still employ large factors of safety, but research has provided data from which to calculate specifications. In days gone by it did not make so much difference if a timber was 12 x 12 when 10 x 10 would have been ample, but that is no longer true. It will become increasingly difficult to obtain large timber and because we now know something of the strength of timber of the various species it has been possible to effect larger savings, which will be surpassed by those of the future. What is true of wood is also true of most other building materials.

Research must also be credited with new types of structural materials which, because of their strength, elasticity and other desirable qualities, can perform heavy duty even in small cross-section and thus reduce weight, which means saving power. Vanadium steel will serve as an illustration. It has done its share in making possible the very serviceable light-weight car; while its machining qualities are such as to make a given finished part cost about one-third the cost of the same part from, say, a high-carbon steel which would have the same strength but which is machined with great difficulty and requires much grinding. As research increases our knowledge of the properties of pure metals and their alloys we will be in an ever better position to eliminate industrial waste, for we shall be better

able to make alloys for each particular purpose and perhaps embody in them qualities which will mean still further savings. Core loss in electrical machinery is a case in point.

IMPROVEMENT IN BOXING AND PACKING

It has been estimated that more than \$55,000,000 is claimed annually from the common carriers for damage done to goods in transit due almost wholly to imperfect boxing and packing. The opportunity to eliminate this waste has been seized upon and research begun. The factors in the problem include the kinds and thickness of woods and the nailing and strapping of the package in relation to the size and weight of the contents. Crates and fiber containers are included. A standardized drum with scientifically placed baffles and other obstructions is used in these investigations to duplicate the strains and stress to which the package is subjected in transit, and while the work has not been completed, much waste has already been eliminated with the co-operation of shippers who have sent their traffic men and packers to become familiar with these newly established data.

An amount nearly as large represents the yearly waste due to losses in seasoning lumber. This waste comes from a lack of knowledge of the fundamental laws underlying timber drying and our inability to design and operate suitable kilns without such information. Research may be relied upon to secure the data.

WATER SOFTENING

There are still many manufacturers who fail to realize what research in water softening has done for them. They continue to waste costly materials in hard water and let their product suffer when the art of water softening has been brought to a very satisfactory stage through research. The more advanced methods for water softening do not involve the use of chemicals from which there might remain residues deleterious to fabrics, etc., and from the commercial softeners development is now turning to the domestic needs. Many textile mills use literally thousands of pounds of soap for water softening without appreciating the fact, and laundries add substantially to this waste.

NEW TYPES OF ILLUMINATION DUE TO RESEARCH

When the statement is made that the country's annual electric light bill would be \$400,000,000 greater if carbon lamps were used today in place of the latest forms of incandescent lamps, only a part of the story is told. To eliminate such an unnecessary expenditure is important indeed, but while the new types of illumination have given more light for our dollar they have also given a quality of light which has made possible a class of work in the absence of daylight that has greatly extended productivity. Present-day lighting is such that practically any plant can go upon a 24-hr. day if conditions make it advisable. It has its effect on office as well as plant, and where costs are high the architect no longer hesitates to count as useful rooms into which the sun never shines. Research in ventilation is playing its part in this same problem and will make possible the elimination of waste time through the great vehicular tunnel which is to connect New York City with the mainland.

But there is another phase of the illumination question.* Even the most improved devices must be properly used. That has been and still is a problem for

research. We have been shown how to place lighting units, the proper use of reflecting surfaces and the most advantageous colors.

WOOD TREATMENT

Research is often called in hurriedly to stop waste and loss. The call is too frequently postponed until the last moment, with fatal results to the enterprise or industry. The damage which marine borers can do has been known for a long time and various treatments for piles have been devised with a view to proofing them against the attacks of these destructive mollusks. It was recorded that marine borers thrive only when the saline content of the water is ten or more grains per gallon. A year or two ago due to drought the level of the rivers emptying into San Francisco Bay fell and salt water in greater concentration than usual entered these streams. Within the year the borer adjusted himself to the new conditions. He fell to work and caused nearly \$20,000,000 worth of damage to marine structures. Piles that had been treated were cut off in a few months. Others treated in the same way endured. Many odd relationships developed. The stake for which research fights the tiny mollusk is large indeed and the scientists are organizing their work to include biology, chemistry and engineering. The problem will be broken up into its several phases and these solved. In time from his work will come fundamental principles and, following these, methods for so building our extensive marine structures as to make them reasonably permanent.

METHANOL, A PROMISING FIELD

Methanol is an important solvent. So far nothing has been found really to take its place and its only source is the destructive distillation of wood. This must be hardwood. Any device for increasing the yield of methanol becomes more and more important as our hardwood supplies are used. Research may show the way to synthetic methanol. It has already been found how to increase the yield 15 per cent without increasing laboratory costs. The laboratory work indicates that by the use of an inexpensive chemical it may be possible to get an increase of 50 per cent in yield. Anything less than the maximum yield naturally gives rise to an industrial waste. The waste in use of this and other solvents is being prevented by solvent recovery according to methods devised in the research laboratory.

TIME AND MATERIAL CONSERVED BY RESEARCH

The conservation of time and material effected by research is just another way of saying that even though prices seem high at times we would not enjoy what we have but for the savings made and the waste thus eliminated. A five-cent piece could not buy a telephone call today but for research, and it would cost more to finish your automobile but for the same agency. Spray systems are quite satisfactory for much painting and finishing work, while modern drying systems permit solvent recovery and temperature control, which are important factors in lowering first cost and insuring satisfactory work.

By the application of the centrifugal clarifier to the varnish industry, rejections of finished materials have been reduced from 50 to 5 per cent and there has been a saving of 80 per cent in labor plus the elimination of much material waste.

It would be difficult to make even a rational guess as to the horse power that has been saved through the use of ball and roller bearing developed in recent years for shafting, heavy machinery, and in many installations requiring continuous duty.

The increase in available horse power per pound of coal via the steam turbine may be properly credited to research. Without question waste will be eliminated in our highway construction as a result of research now under way.

In fact, whatever the field of endeavor, research has effected elimination of waste, and no doubt still greater savings can be made by its continued application. It is certain that waste cannot be eliminated unless we know just where, how and why it occurs. There is no sure way of knowing these things unless we call in research. In the past the most important wastes have been found where least suspected and more waste will be eliminated when our industrialists come to know research better.

Washington, D. C.

Waste Due to Interrupted Production

The amount of idleness or unemployment in industry can be evaluated only through rough estimates. The Committee on Elimination of Waste in Industry stated in its report (July, 1921) that in the best years, even the phenomenal years of 1917 and 1918 at the climax of war-time industrial activities, when plants were working to capacity and when unemployment reached its lowest point in twenty years, there was a margin of unemployment amounting to more than a million men. This margin is fairly permanent; seemingly one or more wage earners out of every forty are always out of work. This unemployment means for the worker a loss in wages, for industry increased overhead due to idle equipment and idle materials, and for the public lessened purchasing power, with all its attendant evils.

During periods of industrial and business depressions unemployment reaches its greatest amount. Such depressions appear more or less regularly at seven or ten year periods and each brings its increase in unemployment and wastage of the productive capacity of industry.

In January, 1921, a nation-wide survey of employment made by the U. S. Employment Service of the Department of Labor showed that there were 6,070,648 workers then employed in industry, as compared with 9,402,000 in January of 1920, a decrease of 3,331,352 or approximately 35.5 per cent.

In addition to minimum and climacteric unemployment, many essential industries show a high unemployment or idleness once a year or oftener. Practically all industries are in a sense seasonal.

Not only does intermittent unemployment reduce the productive capacity of the industry in which it exists, but it brings other wastes. One consequence is a concrete but fallacious industrial philosophy, the "make work" or "lump of work" theory. This is the belief that there is only so much work to be done and that the sensible course of action is to retard production to make employment last throughout the year, or to uphold prices.

Another form of unemployment comes from open conflict between management and labor. Here it should be said that in the past, at least, the amount of waste from the general run of strikes and lockouts through loss of wages and curtailment of production has been less than is popularly supposed.

Waste Due to Lack of Standardization of Chemicals

Careful Standardization of Chemical Products Will Result in Eliminating Misunderstandings Between Buyer and Seller, Will Reduce the Diversity of Products to the Ultimate Advantage of the Consumer and Will Facilitate National and International Trade in Chemicals

By WALLACE P. COHOE
Consulting Chemical Engineer

AS A DIAGNOSTICIAN of sick processes the consulting chemist often finds that loss of production, waste of material and failure to maintain standards of quality in finished products are quite as frequently due to a lax supervision of the raw materials entering into a process as they are to carelessness in the actual manufacturing process itself. Processes which have been running along quietly for years often do get "sick." This may happen suddenly without warning. Hydrogen peroxide becomes effervescent, potassium iodide goes yellow or will not crystallize properly, an azo color goes off shade badly, cotton piece goods will not fill properly, a previously steady-going evaporator suddenly bumps and primes, the lacquer on polished brass peels and flakes, a causticizer will not settle properly and its contents will not filter satisfactorily.

In every plant something of this character happens from time to time. When this does occur, the workman in charge is likely to report to old Bill, the foreman, "Bill, I can't get her up to strength, she ain't going right." To this old Bill is likely to retort, "It's that there new stuff the purchasing agent got last. Get some of the old stuff." But the former material is all used up and they sit up at nights trying to get the process back to normal. Production and quality both drop, so old Bill goes to the superintendent with his troubles. "Say, boss, my department is on the kibosh. That there new stuff oughtn't never to have come into the place."

USE AND ABUSE OF "SPECIFICATIONS"

The superintendent, knowing that many a shrewd idea may hide behind a misused past participle, decides to investigate and checks his specification on the material from the new source, finding that it should give no trouble. He has the laboratory check the former analyses, but no clue to the mystery is found. If there is no plant laboratory, much heated correspondence ensues between the purchasing department and the makers of the product under question.

In the meantime "old Bill" back in the plant is in worse trouble than ever. He cannot get any production worth mentioning and the shipping department is hounding him. It is time for a general inquest. Possibly an outsider has to be called in. It is unnecessary to go into the details of that inquest. We have all attended many. The verdict in the actual case I have in mind did not condemn the new material, but laid the blame upon a too high percentage of iron in one of the heavy chemicals used in the process. This heavy chemical had been purchased for years from the same manufacturer, but a new shipment had not been up to the usual standard. This lapse in quality, in this case by loss of material, loss of customers and expense of investigation, not only ate up the profits of a depart-

ment for a considerable period but caused a loss of confidence in the minds of the selling staff, who naturally disliked the task of explaining to dissatisfied customers.

"But," my critic will retort, "that plant just mentioned was not run properly. Now, in our plant that tank car of blankety blank would have been tested as soon as it was spotted and if not up to specification——." "Specification," that is the word.

It is a fact that where business is properly operated today it does buy and use materials which must come up to a definite specification before they are put into process. The extent to which this practice is carried out is an indication of how far a manufacturer has progressed beyond the rule-of-thumb stage. Some manufacturers buy upon a good specification and leave the matter there, trusting to the manufacturer of the raw material to maintain a specification set forth in the buying contract. This is a dangerous practice and is productive of many losses. Not only must raw materials be bought upon specification, but in this present day when mistakes do occur in spite of most honest intentions, it is necessary thoroughly to examine goods delivered in order to know whether they meet the contract specification.

NEED OF STANDARDIZED SPECIFICATIONS

While it is generally admitted that specifications are common in the buying and selling of chemicals, it may also be truly said that standardization is not general. "But," a manufacturer may say, "why should we worry about standardization if our customers are satisfied with the goods they buy upon specifications which are drawn up to suit their own individual needs?" This point of view is natural, nor is it unreasonable when an industry is in an infant stage and consequently at a time when standardizations are difficult to formulate. If the chemical industry be still an infant industry struggling to find itself, then it is unwise to talk of standardization. Our industry, however, has, we think, emerged from its swaddling clothes, and, if it be not yet a full-grown man, it is at least a hardy stripling, old enough to play the game according to rules.

ADVANTAGES OF STANDARDIZING SPECIFICATIONS

Standards are rules, and rules, like laws, are made not to suit each individual case but rather to yield the greatest good to the greatest number. If a manufacturer of heavy chemicals, for instance, is obliged by his customer to modify his products to suit the individual needs of each individual purchasing them, the result in the end will be a higher price to be paid by each on account of this diversity of product. There is the apocryphal case of the varnish manufacturer who advertised and sold to his customers varnishes which

ran from spar varnish to cheap furniture varnish, all of which came from the same tank in his warehouse. A chemical manufacturer, even if he wished to do something like this, could not, because he is continually being checked by his customer. Is it not possible, however, by careful standardization to reduce the diversity of products to the ultimate advantage of the consumer?

STANDARDIZATION LEADS TO BETTER BUSINESS

Let us examine some of the reasons why standardization makes for better business. Disagreements in business between reasonable men—and the majority of folks in this world are reasonable—usually take place because the two parties to an agreement are not talking about the same thing. A disagreement usually takes place by steps. First, there is moderate protest, then active discussion, upon which follows mutual recriminations and often finally litigation. Both parties are honest; the seller has delivered so much of a certain commodity described in a phrase, while the buyer has received so much of the same commodity, but the meaning of the phrase describing the merchandise in the mind of the seller does not convey the same idea to the mind of the buyer. In other industries this condition has led to the formation of a number of standards. For instance: a fruit grower in western New York may send a consignment of "No. 2 Northern Spy Apples" to England and both he and his English customer understand what the phrase "No. 2 Apples" means.

MISUNDERSTANDINGS RESULTING FROM LACK OF STANDARDIZED GRADES OF CHEMICALS

Up to within the last few years in America the bulk of trading in chemicals has been between the manufacturer of them and another manufacturer who uses them in his own process. Our advent into the larger world trade during the war led to a widening of the field of trading in chemicals. Chemical brokers bought large quantities of chemicals from manufacturers, which they in turn might ship, for instance, to South America or the Far East. A banker in the meantime might be asked to lend money upon warehouse receipts. Numerous disputes arose about and fault was found with the quality of the chemicals being traded in. "C," the customer in the Far East, refused to take delivery of the goods which "B," the broker, had purchased from "A," the original manufacturer, while "D," the banker, was often at a loss to know whether or not he had made a loan upon worthless goods. "A," the manufacturer, and "C," the customer in the Far East, probably each knew what he was talking about. "B," the broker, and "D," the banker, had not this knowledge. If, however, there were available standard specifications describing chemical products, such difficulties as these, which are really encountered in trading and banking, would become reduced to a reasonable minimum.

POINTS TO BE CONSIDERED IN THE STANDARDIZATION OF CHEMICALS

If we are to attempt standardization of the common chemicals which are bought and sold daily there are several points which deserve consideration.

In the first place, any stated standards must be reasonable if such standards are to serve the common good. Such standards must avoid the unnecessary refinements which chemists are rather prone to demand in the products of others.

Secondly, such standards should embody as far as

possible existing practice and should tend toward the simplification rather than a multiplicity of specifications. An attempt was made some years ago by the American Chemical Society to formulate a set of specifications, but this attempt met with no success. Apparently there is no desire on the part of the manufacturers of heavy chemicals for standard specifications, although these same manufacturers are very strict in their demands upon others. It is most natural that these gentlemen should fear a disturbance of their routine by an attempt to standardize these products, and it is the writer's opinion that the growth of a set of standards should be an evolution.

Thirdly, such a set of standards should be so drawn up as to provide for the average consumer. If any particular consumer must demand a specification more stringent than the average, then it would seem reasonable that he should pay the price for the same without putting a burden upon the majority.

Fourthly, a commercial standard should contain the following:

- (a) A terse phrase describing the substance.
- (b) A term accurately setting forth the proportion of the essential material in it.
- (c) A series of grades, by numbers or letters, which will indicate the percentages of extraneous or harmful substances allowed.

STANDARDIZATION OF CHEMICAL PRODUCTS WILL FACILITATE INTERNATIONAL TRADE

We are now at a period when transportation is bringing together the ends of the world, when men widely separated are doing business with one another, and, by the use of standards in many trades, do get along successfully in their commerce with one another. When lumber, wool, cotton, fruit, grain, naval stores and many other things are graded it is unfortunate that in the chemical trade a set of common standards generally agreed to does not exist. Yet we have heard it claimed that chemistry is an exact science.

New York City.

Performance Standardization

The Committee on Elimination of Waste in Industry, Federated American Engineering Societies, in the summary of its report (July, 1921), in dealing with performance standardization states that performance standards should be developed as a valuable aid to planning and production control. Under the week-work system such standards are the basis of a just measurement of the individual worker's performance and of the adjustment of his wage rate to his capacity. Under the piece-rate system they are the basis of just rates. Without standardization of appliances, conditions, work content and method, no valid performance standard can be maintained.

By constantly comparing actual performance with the standards and promptly investigating the causes of the departure from standards, the manufacturer can quickly detect adverse conditions as they creep in, and rectify them. Performance standards, in fact, will enable him to plan the size of his plant and operating force for a given volume of business for continuous operation.

Methods of wage payment should be adopted, equitable and just in their basis, insuring a proper relationship between effort put forth and results achieved by all who participate in the enterprise.

The Personnel Problem: To Eliminate the Waste of Human Effort

Many Wastes of Time and Production Can Be Attributed to Improper Selection and Placement of Personnel and to Management's Failure to Recognize the Value of Training, Transfer and Promotion of Deserving Employees

BY L. B. HOPKINS
Treasurer, the Scott Company

TEN girls worked in a payroll department, computing hours worked and earnings. Each week a line of dissatisfied employees formed at the pay window to complain of errors in pay. Then two other girls, older and more capable, were hired to check the work of the ten younger girls. One day one of these two girls was shifted from inspection to the actual figuring of hours and amounts. For the first week she averaged fifty cards an hour. The younger girls averaged thirty cards an hour. The older girl caught her own mistakes. The younger girls didn't. The two older girls got \$18 a week, and the younger ones got \$15.

The department head did some figuring. The result was that as soon as he could he transferred the ten younger girls, replacing them with the two older girls and four more like them—girls who had a slightly better education and more sense of responsibility in their work. These six girls handled the job that the ten younger girls had been doing and practically eliminated the line of disgruntled employees at the pay window. The result was a direct saving of \$78 a week and an indirect saving of a good deal more.

When the manager asked what had been done to reduce the complaints at the pay window he heard this story. He then told it in a meeting of department heads and said: "There are types of work in all departments that demand specific characteristics in those who are to perform those tasks effectively. In this case it is evidently cheaper to employ a higher grade of help than has been the practice in the past, in order to obtain persons qualified for the work. Some of the rest of you may find something of value in this interesting case."

HIGH LABOR TURNOVER DUE TO IMPROPER PERSONNEL SELECTION

Twenty-five inspectors of small metal parts were required in a machine department of another company. It was not difficult to get men to take these jobs, but it seemed impossible to keep them. They wouldn't stay. The plant superintendent talked to the foreman about his labor turnover. The foreman defended not only himself but the employment office. He convinced the superintendent that as foreman he was not disagreeable, unjust or overbearing. In fact, the superintendent knew him to be a foreman who could get out work and at the same time hold the good will of his employees. But employees didn't stay on the job. The superintendent questioned the foreman about the selection of employees for that work by the employment office. The foreman replied that the employment office was co-operating 100 per cent, and added: "They're

putting a higher grade bunch in there all the time, but they won't stick."

After more study of the causes of turnover in this small parts inspection group it was found that by making the trays smaller and lighter, women could do the work as well as men and that some women would stay on the job. Women who had had a high school education wouldn't stick. They got tired of the everlasting monotony, just as the men had, but women who had had less education and who were nimble fingered frequently liked the work and stayed. After a long period of trial and error, this plant discovered that it is bad business to use too high a grade of help on a job. These are actual cases. They really happened.

SELECTION OF EFFECTIVE WORKERS

One might go on telling all sorts of causes of waste in human effort because the man or woman on the job couldn't do it or didn't like it. They happen all the time. They have been happening for years. They are so common that the causes can be grouped and classified and studied, and they have been. In many cases the general principles for effecting a remedy have been worked out and in a number of instances the technique for avoiding specific mistakes has been developed.

Here, for instance, is an important general principle:

If your workers are to be effective, they must be adapted for and interested in their work. And a force of effective workers is the surest guarantee against inefficiency and wasted effort that a manager can have.

If accountants could set up an inefficiency account that would show all of the minutes of all of the days that employees don't work because they don't want to, plus all of the time wasted in waiting to be told, or in attempting to do that which they are incapable of doing, it would be a startling amount:

Some managers are shocked when told that such waste is to a considerable extent not only avoidable, but absolutely up to them. To allow such waste to continue unchecked is certainly chargeable to inefficiency of management. It is management's responsibility to provide those means already tried and proved elsewhere for eliminating this cause of waste. Furthermore, management is responsible for developing new methods for conserving time now wasted, through study and research. But what are these means that have been proved through actual tryout?

ANALYZING THE REQUIREMENTS OF THE JOB

First of all, it is necessary to know the important requirements of the various jobs. Too often you will hear a job described as one that requires brains, or

guts, or education, or accuracy, or as just a plain-going steady job, or a job where a person must be able to stretch himself when necessary. Frequently an attempt has been made to hit upon the real requirements.

In a New England mill they were hiring persons to learn machine tending who were quick with their fingers. This was a mighty good start, but for a long time they overlooked the fact that short persons couldn't reach to perform some of the operations without standing on a soap box. That is just what the short persons did. After a comparison of output of the two groups—those who used soap boxes and those who didn't—it was evident that length of reach was a factor in success on that job. Simple, you say. Yes, it is, but only after you have recognized that analyzing the requirements of the job means actually finding out what things are needed in individuals to fit them for a particular occupation.

The head of an accounting department complained to the employment office because the handwriting of the new clerks being hired was so poor. The employment office thereafter made applicants copy three or four lines of text onto the application blank. This, they said, gave them a pretty good slant on the applicant's penmanship. It did, but later on it was discovered that many applicants wrote a beautiful hand and at the same time made horrible figures. And in the accounting department the job in question was posting figures day in and day out. Now they request the applicant to copy several numbers of five or six digits each on the application blank, and they know about his ability to make figures before they put him to work on a job where making figures is the chief qualification needed.

STUDYING AND DEVELOPING THE SOURCES OF LABOR SUPPLY

Some jobs require a great deal of the ability to learn and others don't. Some jobs offer a real opportunity to advance, others are out-and-out blind-alley jobs. Unless you can make something more out of your blind-alley jobs, or until you can, it's a mistake, and a wasteful mistake, to put an ambitious person on those jobs. It is just as wasteful to load up positions that bristle with opportunity with persons who haven't the capacity or the desire to go ahead.

With a knowledge of the requirements of the various jobs, the foundation is laid for making wage studies, for developing a promotion program, for establishing training courses and for selecting, placing and transferring employees. Moreover, this knowledge will make it possible to determine whether the applicants for work in your organization are of the right type to supply you with those well suited to the nature of the work in your industry. This is often referred to as "studying and developing your sources of labor supply."

Sally Jones received the following letter one day last spring:

Dear Miss Jones: We are writing to you because you worked for this company for a year and a half. We want to get in touch with those former employees who, like yourself, were able to handle our work in an intelligent and capable way. You know our organization and the kind of work we do. Do you know of any girls who desire a position that you think would make the right type of employee for us?

If you do, won't you give us their names and addresses, or if you prefer, tell them to come into our employment office for an interview and ask for Mr. Smith?

If you would be interested in obtaining a position with us again at any time, please let us know. We should like to have you back with us.

We want to take on a number of capable girls just as fast as we can make room for them in the organization. Very sincerely yours,

FRANK SMITH,
Employment Manager.

Fifty of these letters, made personal by a reference to actual dates of employment or to the correct length of service, built up a most desirable source of supply for a Middle Western company at a time when it was exceedingly difficult to get any help at all. Ministers, priests, doctors, lawyers and retail business men will often appreciate being furnished with a supply of little notes of introduction to the employment manager, that they can give to men or women and boys or girls who desire positions. These and other methods can be used almost anywhere to build up a desirable supply of labor from which selection can be made for positions as they become open in the organization.

VALUE OF MODERN EMPLOYMENT METHODS

The selection of the right persons for your type of work is again not a matter of sleight-of-hand, but involves only the use of quite ordinary and commonsense methods. Nobody is capable of making perfect selections. There isn't any way known of discovering beforehand all that one might want to know about a person who is to be hired. There are men who can avoid a great many of the mistakes that are being made every day in numberless plants and stores and offices where modern employment methods are not in use. These men who can avoid the more common mistakes are not gifted with the power to read minds or any other supernatural power, but they do know the methods needed in employment work and how to use them.

A bright-faced fellow seventeen years old walked into the office of such an employment man a few months ago and asked for a chance in the drafting department. He wanted to learn drafting, he said. The employment office interviewer knew of such an opening and thought he might find in this healthy and hearty youngster a good apprentice for the drafting department.

In the interview it developed that the boy's father was dead and that the boy was carrying out his mother's wishes in trying for a chance to take up drafting. It certainly was to his credit that he wanted to do what his mother wished. The next question brought out the fact that he knew nothing about drafting and had not thought of it until his mother suggested it. His school record raised a doubt as to his qualifications for the drafting room, however, for he had just finished the eighth grade at sixteen and had not moved or had a long sickness during the school period. It at least raised the question as to why he was two years longer in completing eight years of schooling than the normal boy would have been. In a test for alertness, he did rather poorly and he was very poor on the arithmetic questions in the test. The boy was asked to come back the next day. Meanwhile the interviewer 'phoned the boy's teacher and learned that he had always had trouble with mathematics. She added that she couldn't understand his case at all, that he was a good boy, though lively, that he tried hard, she knew, and that everybody liked him that ever met him.

The next day the boy was given a chance, not in the drafting apprentice course, but in the merchandise department. Already his sales are equal to those of some

older men in the department and his personality is adding daily to his own and the company's "good will" in the community. He likes the job and is interested in it.

SELECTING SKILLED LABOR AND TECHNICAL EXPERTS

The selection and placement of skilled labor, retail sales persons, experts in accounting, engineering, chemistry, etc., and professional men offers comparatively little difficulty in picking men qualified for the positions to be filled. Their previous training and experience, their education and achievements are a matter of record that can be easily obtained and checked. The most common error in the placement of such specialists is the all too frequent assumption that a man with an exceptionally good record in his special field will of necessity make a success in another field. A very capable physician may be quite incapable of administering a medical department in industry. A skilled machinist is not qualified, because of that fact alone, to be a foreman. The best chemist in the organization would quite possibly make a mess of the job of office manager.

In this fact lies another important principle of personnel work. Because a man has succeeded in one type of work you have no right to assume that he will succeed in any other situation demanding quite different qualities and abilities.

Let's take your family physician and consider his qualifications for a supervisory position in your business organization. It is to be presumed that you have confidence in his knowledge of medicine, since he is still your family physician. How well is he adapted, as you know him, for the position of department head? Here are some of the qualities which the position of department head demands. How would you rate him in each of these qualities?

RATING A DEPARTMENT HEAD

I. Consider his success in winning confidence and respect through his personality.

II. Consider his success in doing things in new and better ways and in adapting improved methods to his own work.

III. Consider his success in winning the co-operation of men, in welding them into a loyal and effective working unit.

IV. Consider his success in organizing the work of a department, both by delegating authority wisely and by making certain that results are achieved.

V. Consider his success in making his department a smooth running part of the whole organization; his knowledge and appreciation of the problems of other departments.

VI. Consider his success in improving men by imparting information, creating interest, developing talent and arousing ambition.

VII. Consider his success in applying specialized knowledge in his particular field, whether by his own knowledge of ways and means or through his use of sources of information.

It will be interesting, for purposes of comparison, to pick a man from your own organization whom you consider to be very successful in running his department and judge him in terms of these same qualities. It may be that you will find that some of these seven qualities are not particularly well adapted to the requirements of executives and supervisors in your or-

ganization. They were prepared to cover the essential qualities in a specific case, but you can substitute wherever necessary and still discover from actual tryout that even exceptionally capable individuals differ in their abilities and that while they are without question successful in one field, they might be totally unqualified for another.

TRANSFER AND PROMOTION OF EMPLOYEES

It is just as important to recognize that those individuals who have failed in the specific task to which they have been assigned may be assigned to different work and succeed. It has been and still is true that considerable waste is incurred in many organizations by dismissing from the organization men who have fallen down on some specific task. Frequently such men could have been placed elsewhere in positions for which they were fitted, had anybody taken the trouble to discover in what these men were interested and for what their training and experience fitted them.

The management that recognizes its employees as individuals, with different individual abilities, and that endeavors to find the right position for the individual who has been unfortunately placed is developing a type of loyalty and good will in the organization that no amount of propaganda and profit-sharing will obtain. The transferring of employees should not be limited, however, to those who are not getting along well in their present positions. The greatest incentive that can be established for conscientious, effective, whole-hearted service is found in the policy that establishes the principle of promotion within the organization and in the management that sees to it that this principle is put into practice.

This practice is not only an opportunity for management to build up an effective organization, but it is also management's responsibility to the workers, to the community and to the owners of the business. Nor does management's responsibility cease when it has made possible the recognition and promotion of those employees who by their own efforts have succeeded in fitting themselves for greater responsibilities. If it is the policy of the company to obtain intelligent, capable, ambitious employees for those positions where these qualities are needed, then the company should offer the opportunity for these persons to receive training that will fit them to go ahead.

PROPER TRAINING OF EMPLOYEES

Many companies have recognized this responsibility and are conscious of the advantages that accrue from training courses. Because of the pressure of other work and a lack of serious thought on the subject, it too often happens that a most unfortunate waste creeps into the whole training program. This sometimes occurs through the misdirected effort of an overzealous director of training, who enlists as large a number of students as he can, regardless of their capacity to learn or their adaptability to the courses in which they are registered.

Some months ago a manager asked a consultant of his acquaintance to look over the office boy situation in his company. Two of the cases covered in the report are of interest and to a considerable extent are related to that manager's training problems.

Case 1. "Joseph Decker is now fifteen years old. He quit school at fourteen years of age, in the sixth

grade. This suggests that he had difficulty in doing elementary school work. He scored very low in the intelligence tests. The indications are that this boy's mental capacities are limited. He has been urged, however, to take the bookkeeping course and is really attempting to swing it, without much success. Here is an indication that the boy is ambitious and would like to fit himself for more responsible work. The important question is: Are his capacities too limited to enable him to succeed in this work? If so, then it would be wise to transfer him. He is mechanically inclined and interested in the assembly operations in the plant. His interest might be elicited and the opportunity offered him in a suitable training course and a transfer effected to an operating department."

Case 2. "William Brennan is now sixteen years of age. He quit school at thirteen years of age, having completed the eighth grade. He obtained a very high score in the intelligence tests. His schooling and his test score and his service record with the company indicate that he is bright. He is taking a course, on his own initiative, in mechanical drawing, in a night school. He has been an office boy here for a year and a half. It might be desirable to transfer this boy to the engineering and test department, where he could come in closer touch with the company's drafting work."

WASTES DUE TO MISFITS IN SUPERVISORY POSITIONS

In another company a similar investigation was made of the foremen, assistant foremen and supervisors. There were numerous cases found of men who had been excellent workers. Some had been lifted out of work where they were making a real success into supervisory positions for which they were not fitted. Such positions should have been reserved for men qualified to grow into assistant foremanship and foremanship duties and responsibilities. These misfits as supervisors were, however, persuaded to take the foreman's training courses and in some cases they had never mastered the common school work of the seventh and eighth grades.

When you have misfits in supervisory positions, the waste that results from wrong placement is multiplied all along the line. A poor supervisor wastes the time of his superintendent. He wastes the time of his associates. He wastes the time of his workers and frequently this holds up the work of other workers all through the organization.

All of the principles that govern correct personnel work for the rank and file of the workers are applicable in maintaining the executive and supervisory force.

The source of supply for foremen and department heads demands careful study and cultivation. The selection, placement, transfer, promotion and training of these representatives of management all offer a means for keeping the morale of the organization up and the waste of human effort down. If the worker is to be effective in his work, his foreman or department head must certainly be adapted for and interested in his job. And like the worker, those who direct the work of others are themselves entitled to the assurance that their manager will interest himself in their opportunities, their capacities and their desires.

This then is the personnel problem: to develop and co-ordinate the opportunities, capacities and desires of people at work. In the solution of this problem lies, in a great measure, the solution of the problem of reducing the scrap pile of waste time in industry.

Philadelphia, Pa.

Waste Due to Restricted Production

Waste due to restricted production has been analyzed by the Committee on Elimination of Waste in Industry, and the following is an abstract from the summary of its report (July, 1921):

Restriction of individual output for which workers are responsible are susceptible of measurement. They are of two kinds. On the one hand, when workers are scarce the less conscientious workers become independent and slacken speed, whereas when workers are plentiful, they work with greater diligence and care for fear of unemployment. On the other hand, the dread of unemployment is so pronounced that employees engaged in seasonal enterprises frequently restrict production in order to make employment last longer; some workers, moreover, through consideration of their fellow employees limit production to provide work for them, a practice which ultimately results in an economic loss.

Important restrictions of output by employees can result only from collective action. In the building trades, for instance, some painters' unions do not permit of the use of a brush wider than 4½ in. for oil paint, although for certain classes of work a wider brush is more economical.

The tools of the engineer are standard weights and measures, scientifically established. He cannot serve industry unless he can set standards for production and can measure work performed. Many unions now oppose the use of such standards.

Unions are charged with restricting the use of machinery. Painters' unions refuse to allow their men to work on a job where a spraying machine is being used, making claim that the use of the machine is injurious to the health of the workman.

All such restrictions, so far as they prohibit the use of the best and most efficient machine, constitute limitations of output. The actions of most unions, however, are confined to the restriction of the use of machinery rather than its prohibition.

RELATION BETWEEN MANAGEMENT AND WORKERS

Management has a definite responsibility in selecting, upgrading and maintaining personnel.

Experience indicates that the best results can be obtained when employment and personnel direction develops a sense of mutual interest in production on the part of management and workers. To accomplish this management should stimulate the interest of workers, individually and collectively, in creation, in craftsmanship and in the contribution of their experience and knowledge to the productive processes. "Industrial relations" to be effective should be closely allied to production and concern itself with educating the workman in the science of process, recording his accomplishment and enabling him to become conscious of the relationship of his work to the whole.

During the past few years there has been a widespread advance in extension of employment and personnel methods in industry and many of the accruing advantages are now generally known. Among these is a means whereby the worker has a direct avenue of approach to his employer, and the employer has a means for communicating organization policies to the employee. Such industrial education and training as has been conducted by certain leading manufacturers has obtained beneficial results, and it is believed that further developments along these lines is desirable.

Disclosing Waste Through Better Cost Methods

Many Industrial Failures Are Traceable to Blind Dependence on Cost Determined by Rule-of-Thumb Methods—Modern Cost Systems Will Disclose Waste in Unprofitable Products, Idle Labor and Machinery and Erroneous Methods

BY ERNEST J. WESSEN

Industrial Engineer, W. T. Rawleigh Company

IT IS scarcely necessary to urge the need of accurate cost determination. If the voluminous literature which has been dedicated to this subject, the hundreds of articles which have appeared in technical journals, pages of advertising, to say nothing of the pretty little pamphlets brought with each mail, have not educated the industrial executive to the real need for accurate cost knowledge, then certainly existent economic conditions have.

The progressive manufacturer keenly realizes that if he is to survive the coming aggressive and intensive competitive era, he must not only know what his product costs him, but—of more importance—he must have such control over his manufacturing operations as will enable him to keep his costs at minimum levels. Without a comprehensive knowledge of his costs, he will be unable intelligently to compete with those who have provided adequate cost control, and must inevitably meet defeat at the hands of his progressive competitors. It is scarcely possible to overstate the case in urging the need for cost knowledge.

VALUE OF DETAILED MANUFACTURING COSTS

The value of accurate detailed manufacturing costs may be divided into two phases: First, the commercial value arising from the necessity of having an accurate knowledge of costs in order that selling prices may be intelligently fixed. Second, the technical value to the management in placing at its disposal pertinent cost data enabling the manufacturing executive to establish proper control over manufacturing operations. The greatest value of cost information to industry is its technical value.

It is not impossible or indeed extremely difficult for manufacturers to approximate closely the cost of the finished article by rule-of-thumb methods. In fact, if he is painstaking, his results may be startlingly close to those obtained by more complex methods. However, this is the exception rather than the rule. A large percentage of industrial failures due to managerial incompetence can be traced to blind dependence on costs arrived at through antiquated rule-of-thumb methods.

Granted that we arrive at exceedingly accurate costs of finished products by rule-of-thumb methods of estimation, this is of no avail if we lack sufficient control over our manufacturing operations to enable us to meet our competitors' prices. Indeed, few healthy, industrial executives are satisfied with trailing their competitors; most of them prefer to take the lead. The lead cannot be taken and held without manufacturing control, and manufacturing control cannot be established without detailed cost data. Obviously, there is only one way to obtain this information—through a cost system.

The successful cost system must isolate the various

elements of factory costs in such a manner as to permit the manager to make a quick and accurate analysis of manufacturing conditions. The figures obtained must be of a current rather than of a historical nature. In other words, the results must be compiled and placed in the hands of the executive in ample time to permit the establishment of positive control over current operations. The progressive manager is not concerned in what has been done, but in that which is being done. The system must further provide for the establishment of cost standards by which subsequent costs may be controlled.

Such a system will disclose unprofitable products, waste, idle machinery, idle labor and erroneous methods. It will enable the management to formulate policies and assist in successfully carrying out such policies. Standardized costs will be established, comparative economy of operations ascertained. It will be possible to place the factory on a budget basis. Selling prices may be fixed with confidence—in fact, profits practically assured under normal conditions. Indeed, once such figures have been made available they become indispensable.

SYSTEM SHOULD BE SIMPLE

The efficient cost system is as simple as is consistent with sound manufacturing practice; all frills are eliminated. Its operating cost is extremely low as compared to the returns received; hence it is productive. Cost figures are sufficiently detailed as to render intelligent deduction practical, but not in too great detail. Extremely elaborate analysis of cost is seldom justified. Cost figures obtained are accurate within the bounds of feasibility. Accuracy in costs must be striven for, but strictly speaking is unattainable. In short, the system must be eminently practical.

It is not a difficult task to install such a system; the expense is not great and the need for it is fully recognized. Despite this the Federal Trade Commission states that out of 250,000 manufacturers in the United States but 12,000 have adopted some sort of a cost system. Ninety-five per cent of our manufacturers facing unknown conditions without a knowledge of their costs, in other words, entering upon uncharted seas without a compass! Clearly this apparently apathetic attitude on the part of American manufacturers must be due to some well-founded cause, especially in the light of the great publicity which this subject has been given.

The cause for this reluctance on the part of manufacturers to adopt modern cost methods is easily found. In the first place the results obtained from the average cost system have not justified the claims made for it at the time the system was sold to the manufacturer.

Many worthless but expensive systems have been foisted upon industry.

FAILURE OF MODERN COST PRACTICE

If we accept all cost systems in operation today as representative applications of modern cost practice, then modern cost practice has failed. There are, of course, many excellent systems in operation, but that the majority of those installed during the past five years have failed is not to be denied. Their failure has been so complete as to arouse doubts in the minds of industrial executives as to the soundness of the fundamental principles upon which these systems were based. In this fact will be found one of the major reasons for the reluctance to adopt modern cost methods.

We shall not undertake to cite here the innumerable ways in which cost systems have failed, in many cases disastrously. It will suffice to say that failures have been so numerous and in some cases so ludicrous as to destroy the confidence of many manufacturers in the judgment of those who are supporting the movement for "better cost methods." That the majority of systems in operation have failed and proved impracticable is not to be denied. However, the failures are not due to inherent defects in fundamentals. Probably another factor tending to further the apathetic attitude of manufacturers has been the apparent incompetence of many of those attempting to further the movement. This latter condition as well as the failures of so many systems can be attributed to nothing other than the conditions existent at the time the movement for manufacturing costs received its greatest impetus.

HISTORY OF MODERN COST METHODS

Probably no other phase of industrial management has been born under such unfavorable conditions as cost finding. Prior to 1917 there were few cost systems in the United States worthy of the name. Here and there would be found a system maintained largely for its commercial value. It was looked upon by most manufacturers as an expensive fad, and at the time we entered the World War cost finding was practically unknown.

After April 6, 1917, and until October of the same year the War Department made practically no attempt to obtain immediate production. According to Benedict Crowell, Assistant Secretary of War, "the department was engaged in determining requirements and formulating plans for mass production." ("America's Munitions.")

In October the department's plans had been formulated and the awarding of contracts began in earnest. During the preparatory period the cost-plus contract had been decided upon as the most equitable basis upon which war material might be obtained. In a few months time the Ordnance Department alone had in force 8,000 of this type of contract, the Signal Corps, with the Aircraft Division, as many more. The Quartermaster Corps Construction Division and other branches also awarded large numbers of these contracts. A conservative estimate would fix the total number of these contracts in effect during the early months of 1918 at 25,000. Many manufacturers had more than one active contract, but it is a safe assumption that these contracts were divided among not less than 15,000 manufacturers.

The accurate determination of manufacturing costs is essential to successful operation under the cost-plus type of contract. The preliminary studies of the War Department had shown the officials that it would be necessary to maintain a large staff of cost accountants to check manufacturing costs under this type of agreement. Accordingly in September the Ordnance Department attempted to obtain the services of over 1,000 cost accountants. In October and November the Signal Corps alone employed 700 cost accountants, and in a few months' time the War Department had employed several thousand men as cost accountants. Not all of them bore this title, it is true; some were production experts, some accountants and others appeared under other classifications, but they were all employed for cost work. The different titles were used to open the non-competitive positions of the Civil Service to those who could not meet the far from exacting requirements of the Civil Service Commission.

It was just as essential to the manufacturer that he too be equipped with means for determining his manufacturing costs as it was to the Government that it have its cost men. Although some contractors performed work of such a simple nature as not to require the services of a cost man, we can safely estimate the number of cost accountants employed by industry during the latter part of 1917 and early months of 1918 at 7,500. This was the real birth of cost accounting.

In a short period of but a few months no less than twelve or fifteen thousand men were employed as cost accountants. Where did they come from? With only several hundred cost systems in operation, we know that as a rule they came without previous experience in the work which they were to take up. It is interesting to note just how these cost executives were obtained.

PLACES FILLED WITH ILL-EQUIPPED YOUTHS

The accountants in charge of the cost-accounting sections of the various War Department offices first endeavored to obtain trained accountants for the supervisory positions, but hundreds of these men were required by the regular accounting branches and with the selective draft and only a small number to draw upon this source was soon exhausted. Men with book-keeping experience and executive clerks were next called upon and so on, until we find the positions of assistant cost accountant and cost clerk filled by young men still clutching their business college diplomas in their right hand. The same conditions existed in the cost organizations built up by manufacturers. Are we to wonder that we are today finding the systems installed by these well-intentioned young men defective?

Under certain conditions it might have been possible to build up this force of men from the ranks of those particularly fitted to take up the work of the cost executive. On the other hand, those fitted for this class of work were in urgent demand for other phases of war work.

That this group of men failed in the task assigned them will be evidenced by an inspection of the records of the U. S. Court of Claims. Their task was to obtain cost data sufficiently comprehensive and authoritative to form a basis for the adjudication of the claims of those manufacturing under cost-plus contracts. A comparatively simple task when we think of the task we have assigned the present-day cost exec-

utives. Nevertheless, due to faulty cost data, wrangles over cost elements and other causes, the Court of Claims has many cases still awaiting settlement. All of this as well as present conditions are due to the fact that those selected for the work did not possess the essential qualifications of the cost executive.

ESSENTIAL QUALIFICATIONS OF COST EXECUTIVE

The clerk with an aptitude for figures and detail or the accountant whose experience has been confined within the limits of accountancy is not qualified to assume the duties of a cost executive except in so far as his personal characteristics may qualify him for that work. Indeed, at present few men will be found who possess all of the essential qualifications of the cost executive.

This indispensable member of the progressive industrial organization must be of the executive type. He must be at once aggressive and tactful, courageous and loyal. He must possess resourcefulness and originality, imagination and initiative. It is scarcely necessary to add that he must be reliable and honest.

So much for the general qualifications. Many executives in all industrial activities possess these desirable characteristics, but the cost executive must possess many essential qualifications obtained only through training and experience. The present low level of efficiency of most cost departments is due largely to the failure of manufacturers to consider these special qualifications in selecting their cost executives.

KNOWLEDGE OF SHOP AND ENGINEERING PRACTICE ESSENTIAL

A good knowledge of shop practice is necessary. Without this knowledge, even the most simple problems of cost finding cannot be treated intelligently. A superficial knowledge will not suffice. Unless he is familiar with shop practice, the entire system will be operated upon a conjectural basis.

A knowledge of engineering practice is indispensable. It is at least difficult to imagine one without this knowledge successfully determining power costs and making intelligent distributions of these costs, particularly where high-pressure steam and exhaust steam are used in large quantities in the manufacturing processes. Depreciation, obsolescence and depletion rates can be intelligently fixed only by one having at least some knowledge of engineering fundamentals. Burden distribution is essentially an engineering problem requiring engineering treatment, and last, he must establish standards with the precision of an engineer.

COST EXECUTIVE SHOULD BE ANALYTICAL AND HAVE KNOWLEDGE OF STATISTICAL LAWS

The cost executive must above all be analytical. He must be able to interpret cost data into terms sufficiently clear to arouse the management to immediate action. He must know what is pertinent and be able to isolate such facts from the mass of cost information flowing through his department. His studies and resultant cost reports must be exhaustive. Above all he must analyze his figures with a detached viewpoint.

The compilation of cost data requires statistical treatment. Certainly it is a phase of statistics. Without a knowledge of statistical laws on the part of the compiler, cost statements are of little value and apt to be misleading. Frequency, dispersion, correlation and other phases of statistics enter into the cost executive's

daily work. By statistics we do not mean graphical presentation. So much has the word statistics been abused that the average industrial executive has come to look upon one who prepares attractive graphical charts as a finished statistician. Although these charts are valuable if intelligently prepared and not overdone they are not essential to successful cost finding and something more than the ability to draw charts is required of the cost executive along statistical lines.

The science of accounting provides for the exact recordation of known business transactions or facts. With the engineer's training and the knowledge of the statistician the cost executive is called upon to determine facts by means of approximation and averages. The accountant shuns this practice and denies that accuracy is unattainable. The successful cost executive realizes that he cannot attain accuracy, hence he establishes standards of accuracy and attempts to approach these standards in his daily work.

KNOWLEDGE OF ACCOUNTING OF MINOR IMPORTANCE

Last and of least importance, the cost executive should have a knowledge of the theory of accounts and practical accounting. One possessing the qualifications outlined in the foregoing will have no difficulty in rapidly mastering sufficient accounting knowledge to enable him to supervise the allocation and posting of results obtained by his system.

All of the above pertains largely to the operation of existing systems. As for the design and installation of a practical cost system, it is essentially the work of an engineer. To design a comprehensive system for the average factory manufacturing a multiplicity of products calls for engineering training and constructive ability. Even staid firms of public accountants now recognize this fact and their cost men are as a rule called cost engineers or some similar term from which the word accountant has disappeared.

FAILURE OF SCHOOLS OF COST ACCOUNTANCY

Where may men possessing the above qualifications be obtained in sufficient numbers to place industrial cost determination on a sound basis? Certainly not from schools. The writer recently examined the curricula of a number of well-known schools teaching cost accountancy. The following is representative and is the course of study adopted in one of the best known accounting schools in the United States:

Requirement for matriculation—high school diploma.

Sixty class periods in twenty weeks.

Studies:

Theory of accounts.

Practical accounting.

Auditing.

Law.

Economics and finance.

Can we imagine the ambitious young man applying these teachings in determining production centers, ascertaining power costs, or coping with complex burden problems? No! As a matter of fact accountants have failed to apply even good practical accountancy to their work in cost departments. Had burden reserves been established in 1917 by those to whom fell the task of developing practical cost methods for industry, our whole economic structure might have been favorably changed and surely the effects of the present period of depression would not have been so disastrous to many of the 250 industrial concerns which have failed during the past six months.

Cost practice must conform to the principles of accountancy in so far as the actual recordation of ultimate cost elements are concerned. Beyond this cost finding is not a function of the accounting department. The successful cost man is a natural executive, an engineer by training with a knowledge of statistics and familiar with the fundamentals of accountancy. We shall not be able to obtain men with these qualifications readily—in fact, they will have to be developed. For the present, the task of setting cost finding on a sound practical basis is directly up to the manufacturer and the technicians forming his present organization. The task is not difficult or expensive.

REMEDIAL MEASURES

In the majority of industrial organizations will be found individuals competent to solve different phases of our cost problem. By organizing these men into a group and properly co-ordinating their efforts we shall obtain a functional group competent to consider the problem before them and arrive at a practical solution. Its task will be the development of the new system or the simplification and improvement of an existing system. This group should be known as the cost committee or board.

The specific duties of the cost committee would be to determine the general method to be followed in cost finding. It should then fix production centers (if required) and develop media for the collection of costs. It would be its problem to arrive at the various methods to be followed in the determination of and distribution of burden. It would decide upon and develop a practical system of tabular and graphical reports for transmitting cost intelligence to the management. After the fundamentals had been established the actual task of compiling cost data would be delegated to a cost department headed by a capable executive working under the committee's instructions. The committee should not find it necessary to devote more than a few hours each week to its task.

In this manner a practical cost system can be developed and cost standards established. However, this in itself is not enough. We must have some method of checking standards—in short, manufacturers must establish common standards. Again, not all organizations have all of the men necessary to make up a complete cost committee. The incomplete committee seeking advice on certain phases of its work, as well as the committee seeking common cost standards, must go outside of its own organization for assistance and advice.

MANY ORGANIZATIONS COULD AID

In this connection there are many organizations that can render service of inestimable value to the manufacturer by assisting in the determination of common cost standards and standard cost practice and helping the manufacturer in his effort to obtain a practical cost system. These organizations may be divided into six groups:

1. Community industrial organizations.
2. State and national manufacturers and trade associations.
3. Technical societies.
4. Industrial cost associations.
5. Manufacturers of machine tools and equipment.
6. Federal bodies.

Due to economic conditions nearly every manufactur-

ing community houses several plants manufacturing similar products. This should prove of great value to the manufacturer in aiding him to arrive at proper cost methods. Through the exchange of ideas and discussion of their cost problems at community manufacturers' associations, the cost committee would be greatly aided in its work. Conditions as to labor and material costs vary among communities, hence community common cost standards would prove of greater value to the local manufacturer than national standards. However, both standards are necessary for comparative purposes, the national common cost standards serving as a check on local standards. The Rochester Industrial Management Council and such groups as the Sherman (Tex.) organization of industrial managers are excellent examples of what may be accomplished through the organization of industrial executives in the community.

NATIONAL TRADE ASSOCIATIONS

National trade organizations are rendering a wonderful service in the development of uniform cost methods. Already many systems have been developed along practical lines and adopted. This means standardized cost practice and common cost standards and to many manufacturers has proved to be the solution to their cost problem. However, it is of tremendous importance that the national executives of these organizations exercise good judgment in the selection of uniform methods. Several of these uniform systems are open to the same criticisms as has been applied to our present general cost methods. Associations having uniform cost methods adopted several years ago upon the advice of consultants might well examine these methods for defects and take the necessary corrective measures where defects are found.

TECHNICAL SOCIETIES

There are ten different terms for "burden," eight different expressions used in lieu of "direct labor" or "direct material." The very word "cost" has not been clearly defined. There is no general agreement as to where factory costs start and stop. At least twenty-five different methods are offered for use in determining depreciation rates and four recent authors are at variance as to the method of determining material costs. Standards must be established. The various standardization committees of the technical societies can accomplish a great deal along this line. The American Society of Mechanical Engineers could render a great service by determining and publishing depreciation rates on standard equipment, while the American Society of Civil Engineers might render a similar service with reference to the depreciation rates on structures.

INDUSTRIAL COST ASSOCIATIONS

Recognizing the urgent need for a better knowledge and control of costs, the Industrial Cost Association, with headquarters at Pittsburgh, was organized a little over a year ago. The membership is limited to manufacturers and managers of industrial corporations, firms, trade associations and employees in executive supervision of their cost methods. The aims of the association are to stimulate interest of manufacturers in correctly determining costs, standardize terminology, establish basis principles, simplify cost accounting and educate members in the use of modern methods of cost

analysis and control. The growth in membership of this national body has been rapid and is an excellent indication of the intense interest manufacturers are taking in the correct determination of costs. Much progress has already been made by this association, and there is no question that it will be a powerful factor in placing cost determination on a sound and practical basis.

Little, if any, progress has been made in five years in the formulation of sound principles for the determination of depreciation rates. Ardent advocates of any one of twenty or thirty different methods of determining the depreciation rates applicable to items of plant and equipment will be found in any industrial community. Even the accountants in the Internal Revenue Department have failed to clarify the situation as regards income tax deductions. However, as stated before, this is not an accounting problem.

MAKERS OF MACHINE TOOLS AND EQUIPMENT

By working in conjunction with technical societies the manufacturers of machine tools and equipment can dispel a great deal of the confusion existing at this time. Their files contain ample data from which authoritative information covering the life of their product under various conditions might be compiled. Such information published in a form similar to that adopted by the National Electric Light Association in connection with power requirements of equipment would greatly simplify one of the cost executive's most vexatious problems.

FEDERAL BODIES

Much valuable information which would be of great assistance in standardizing cost methods is stored away in the governmental archives at Washington. The act of Sept. 26, 1914, and later the Clayton act authorize the Federal Trade Commission to make public from time to time such information as it shall deem expedient in the public interest. The aid of this commission has been proffered to industry a number of times by its former chairmen. The intelligent preparation and publication of bulletins on cost methods would greatly increase the value of this commission to the public.

It has first-hand experience and knowledge with many existing systems. This commission could furnish a great deal of authoritative information on the establishment of the necessary reserves required by sound cost practice. Other departments, such as the Bureau of Standards, could render real service along various lines, all with the purpose of placing industry on a sound basis of cost control. With the intelligent co-operation of the above-mentioned bodies and a distribution of technical cost functions among those members of industrial organizations qualified to perform these functions an accurate practical cost system is easily attained.

UNTOLD MILLIONS LOST THROUGH LACK OF PROPER COST METHOD

During the past five years lack of proper cost methods has cost American industry millions upon millions of dollars. Unless manufacturers take the necessary steps to fortify themselves with a sound basis for the fixation of selling prices and, of more importance, provide means by which they can intelligently control their manufacturing operations it is but a matter of a

few years before such manufacturers will be eliminated by their more farsighted competitors.

Industrial executives who have blind faith in their existing cost system will do well to examine into methods used and take the necessary corrective measures to place their house in order. In many of the most progressive manufacturing institutions in the country it will be found that the much-vaunted savings effected by industrial engineers or men holding kindred positions will be nearly offset by making a proper redistribution of burden rates over the period of abnormal production. Through the application of inadequate burden rates on overloaded plant facilities the manufacturer has been left "holding the bag" during the present period of depression. It is his move! To avoid a checkmate or at least to escape a stalemate at the hands of his progressive competitor he must move intelligently and quickly.

Once methods have been established and proved sound they should be adhered to despite the wailing of impractical theoreticians. It should always be borne in mind that actual costs cannot be definitely established, but practical costs are within the reach of all.

Freeport, Ill.

Opportunity for Governmental Assistance in Waste Elimination

The opportunity for governmental assistance in waste elimination has been outlined by the Committee on Elimination of Waste in Industry in the summary of its report (July, 1921). It recommends the establishment of a national industrial information service, a national statistical service, a body of principles for the adjustment of labor disputes and a nation-wide program of industrial standardization.

A national industrial information service should furnish timely, regular and complete information on current production, consumption and available stocks of commodities, supplementing the work of private agencies.

A national statistical service should be established and maintained covering employment requirements and conditions throughout the country. The fundamental knowledge required to make a correct analysis of unemployment in any period is not at present obtainable. The meager information for such a study has to be collected from many agencies. These are under no central control, they are often not in contact and frequently duplicate effort.

A body of principles for the adjustment of labor disputes should be accepted which can be developed with experience. Thus far American legislation for the settlement of these problems presents almost as many varieties as there are states.

A nation-wide program of industrial standardization should be encouraged by the government in co-operation with industry. In the standardization of design of product, methods of procedure and number of models, there rests a large opportunity for the reduction of waste. It is not sufficient, however, to attempt to standardize the product of a given industry, for almost every industry is so dependent upon others that they too must co-operate. The Federal Government could call together the representatives of the trade associations of interdependent industries and in co-operation form committees for this purpose. The opinions or decisions of such committees might from time to time be promulgated as standards of practice.

The Elimination of Construction Wastes

A Comprehensive, Dollars and Cents Analysis of the Preventable Wastes in the Construction Industries and a Thorough Understanding of the Responsibility Imposed Upon the Contractor, Owner, Architect, Engineer and Workman

BY GEORGE W. BURPEE

Vice-President, Dwight P. Robinson & Co., Inc.

WASTE exists in the construction industry as in other industries, and, it may be, to a greater extent due to the peculiar conditions surrounding construction operations. The relatively short duration of each job entails an almost continuous process of organizing and reorganizing, building up a working force on a small nucleus, and in numerous cases moving a force from one section to another.

For the purposes of this article, only those phases of the construction industry have been considered which pertain to the assembly of materials of construction into the completed work. No attempt is made to cover the manufacturing or merchandizing of building materials.

The number of men engaged in the United States in the construction industry thus defined is estimated for the year 1919 by the Prudential Insurance Co. at 1,575,000, as compared with a total working population of 42,503,000. The number of workmen employed in the construction industry is exceeded only by the numbers employed in agricultural pursuits, general manufacturing and steam railways.

The annual expenditure involved in the construction industry in the United States for the years 1919 and 1920 is estimated to be \$3,640,000,000. The statistics available for the first six months of 1921 indicate that expenditures for this year will not be much less. These figures will be used for purposes of argument with the realization that prices both of materials and labor are above normal.

The sources of waste considered in this article are those due to the customary manner of letting contracts, to the abnormal risk in the construction business, artificial restriction of output, intermittence of employment, labor turnover, use of construction plant and tools and a few other miscellaneous causes.

WASTE DUE TO THE MANNER OF LETTING CONTRACTS

Considered in the chronological order in which waste appears on any construction undertaking, the manner of awarding the contract comes first.

The general procedure on building work is this: The owner, either directly or through his architect or engineer, prepares plans and specifications for the project in mind and invites contractors to submit bids for the complete work. The contractor must take the plans, determine in detail the quantities of each item involved in the project, fix the unit prices for which he believes the work can be performed, prepare the estimate for the entire project and submit his proposal.

From observation and experience, it is estimated that an average of eight general contractors submit proposals on each project and an average of two and one-half sub-contractors in turn furnish proposals to each

general contractor for each of the items of the project to be sublet—a total of twenty to the eight general contractors. If bidding on building work, each of the eight general contractors must prepare a quantity survey for the entire project and each of the sub-contractors must prepare a quantity survey to cover the item on which he proposes to bid. Here is one of the greatest wastes in the construction industry and one of the wastes which can be easily eliminated by having the quantity survey prepared by the architect or engineer, as is the common practice on engineering projects.

The cost of preparing the quantity survey to each general contractor and his corresponding sub-contractors is estimated to range from \$500 to \$1,500 for each \$1,000,000 involved, or, for eight general contractors, a total of \$4,000 to \$12,000 for each \$1,000,000 involved in a contemplated project. This cost does not include any allowance to the contractor for determining the price for which he will perform the work, since that cost must be incurred by each contractor even if he is supplied with a quantity survey. If the quantity survey be prepared by the owner's architect or engineer, the cost of one operation only will be incurred and the saving for each \$1,000,000 of contemplated work will be \$3,500 to \$10,500.

The total contemplated work for the United States—that is, work on which bids were requested—for the years 1919 and 1920, based on the F. W. Dodge Co. statistics for the twenty-seven northeastern states, is estimated at \$6,200,000,000 and \$7,000,000,000 respectively. An approximate figure of \$6,000,000,000 will be used. Of this total more than three-quarters represents building work on which lump sum bids are requested, as compared with less than one-quarter, which represents engineering projects to be let on unit price or cost plus a fee basis. Assuming that \$4,500,000,000 worth of work is tendered for, that an average of eight general contractors bid and that the cost of preparing each quantity survey is \$500 per \$1,000,000 of the estimate, then the total cost of making the quantity surveys for this volume of work would amount to \$18,000,000, of which all but \$2,250,000, or say \$16,000,000, would represent waste due to multiplication of effort.

WASTE DUE TO THE ABNORMAL RISK IN THE CONSTRUCTION INDUSTRY

It has been estimated on the basis of income tax returns that the risk involved in the construction industry is extreme when compared with manufacturing, commercial pursuits, mining and quarrying. These sources of information show that in manufacturing industry the loss is 3c. for every dollar of gain; in trading, mining and quarrying, 7c. for every dollar of

gain; while in the construction industry, the loss is 25c. for every dollar of gain.

The total volume of work performed in the United States during 1920 has been previously estimated at \$3,640,000,000. Of this total, probably 4 per cent would represent net profit, say \$145,000,000. At the ratio of 25c. to one dollar, the corresponding loss would be approximately \$36,000,000. That the construction industry can be placed on a plane of no business loss or even that it can be placed on a plane of as small a loss as manufacturing, mining, quarrying, trading, etc., is not to be expected, but it seems reasonable that it can and should reach a plane where the loss would not be greater than 10c. instead of 25c. on every dollar of profit in new construction. On such a basis, the loss would be \$14,500,000 instead of \$36,000,000, or a saving of \$21,500,000.

The causes of abnormal losses in the construction industry include the natural tendency to let work to the lowest bidder unless there is some positive reason for not considering his bid, ambiguous plans and specifications which leave room for doubt as to their interpretation and lack of a quantity survey supplied by the owner, and the practice of requiring lump sum bids where quantities are not definitely ascertainable and working conditions cannot be foreseen.

The remedies for these losses consist of a thorough investigation of the contractor before letting the contract, the furnishing of a quantity survey by the owner which will insure all contractors bidding on the same quantities, the standardizing of specifications so that they will mean the same thing to different contractors, letting work on unit price or on cost plus a fee basis when quantities are not ascertainable and conditions unknown.

WASTE DUE TO ACCIDENTS TO WORKMEN

Forty-two of the forty-eight states in the Union have passed employers' liability or workmen's compensation acts which hold the employer liable for accidents incurred by workmen in his employ. The compensation acts provide for the payments to be made to the workman, the safeguards with which the employer is to surround his operations and, through the state insurance commissioner, the rates which are to be charged by the insurance and indemnity companies for carrying the employers' liability or workmen's compensation insurance.

The amount of such insurance which the contractor must carry ranges from about 3 to 10 per cent of the payroll. The rates vary quite decidedly for different states. For instance, the rates for New Jersey, a low-rate state, compared with those for New York, a high-rate state, for some of the commoner building trades are:

	Rates per \$100 of Payroll	
	New Jersey	New York
Masonry.....	\$3.36	\$8.30
Concrete work on buildings.....	2.94	7.49
Carpentry work outside.....	3.51	11.564
Carpentry work inside.....	0.70	2.102
Structural steel workers.....	9.07	27.569
Grading.....	0.98	2.397
Cellar excavation less than 12 ft. deep, no subaqueous work or blasting.....	1.15	2.76
Blasting.....	13.83	22.80
Millwright work.....	1.72	3.833
Miscellaneous labor.....	1.72	3.833
Supervision, including superintendents and engineers.....	1.19	1.560

An average rate may be conservatively estimated at 4 per cent of the payroll cost. It has been pointed out that the total volume of construction business carried on in the United States during 1920 was roughly \$3,640,000,000. Assuming a ratio of labor to total cost of work of 1 to 4, the payrolls for this work would aggregate approximately \$910,000,000. At a rate of 4 per cent the total cost of compensation insurance would be, say, \$36,000,000.

WASTE DUE TO RESTRICTION OF OUTPUT BY LABOR ORGANIZATIONS

An extremely serious cause of waste in the construction industry is due to restriction of output by labor organizations. This is an economic waste which directly affects the owner but indirectly affects the workman himself, since the resulting waste of capital prevents its use for other production, which in turn would offer increased opportunities for employment.

Those who are interested in a more detailed treatment of this particular phase of economic waste in the construction industry are referred to a splendid paper presented by Charles R. Gow of Boston before the Boston Society of Civil Engineers on March 24, 1921. Mr. Gow estimates that the restrictions imposed in Boston by labor organizations increase the cost of building at least 25 per cent. The average for the entire United States, however, would probably be closer to 10 per cent. On this basis, on the approximate volume of construction work completed during 1920, \$3,640,000,000, the waste would amount to \$36,000,000.

WASTE DUE TO INTERMITTENCE OF EMPLOYMENT

Another most serious economic waste in the construction industry is intermittence of employment. This is classed by the Committee on Elimination of Waste in Industry of the American Engineering Council as the greatest waste in the construction industry, and considering that the loss is suffered by owners, contractors and workmen, this is very probably true. The comparatively short period of employment of workmen in the building trades throughout the year is not generally recognized.

If by some means the building period could be distributed more nearly over the entire year, instead of being bunched in about eight months, it is probable that labor would accept a slight reduction in hourly rate so long as the yearly earnings would not be reduced. The result would be that the owner would be paying for net time worked instead of for such a high percentage of idle time as well. Take the carpenter as the typical case. He works 73 per cent of the year. If his work could be distributed so as to enable him to work 90 per cent of the year for the same total earnings, the saving to industry would be 17 per cent of his annual earnings. This ratio applied to the total estimated labor payroll of approximately \$900,000,000 for 1920 would be \$15,300,000.

WASTE DUE TO LABOR TURNOVER

A loss closely allied to the waste due to intermittence of employment is the loss through changing personnel of employees, commonly called labor turnover. The losses due to this labor turnover are greatest during periods of scarcity of labor, since the tendency during those periods is for workmen to feel more independent, to be less efficient and quicker to move from

one employer to another. Consequently it is difficult to determine with any degree of accuracy what the losses due to this turnover are. Some approximation, however, may be made to indicate the possibilities. Assuming 1,575,000 men engaged in the construction industry and an average number of engagements for each man per year of four, the total number of men engaged would be 6,300,000. If the average number of engagements per year could be reduced to three, the saving would be 1,575,000 engagements a year, and if each engagement cost only \$5, including the cost of employment bureau and the cost of training the new man to his work, the total loss to the contractor alone, neglecting entirely the loss to the workman, would be about \$8,000,000.

WASTE DUE TO LACK OF PROPER COST ACCOUNTING

Another waste in the construction industry which may correctly be attributed to incompetent administration is extravagance in the use of both materials and labor. The most effective means of controlling such waste has proved to be the maintenance of accurate and promptly available records of materials used, and unit costs of labor involved in installation. There is nothing new about such cost accounting, but it is not a rash assumption that numerous contractors apparently carrying on work with a high degree of success are not taking advantage of a proper accounting system which would enable them to effect considerable savings for themselves and the owners.

On large undertakings this saving might amount to 10 per cent or more of the total payroll. On the job of average size of \$30,000 the saving would be less in proportion. For all work the saving would probably average 4 to 5 per cent per year or, say, roughly \$4,000,000.

WASTE DUE TO IMPROPER CONSTRUCTION EQUIPMENT

The average cost to a construction undertaking for the use of construction equipment is approximately 1½ per cent of the total cost of the work. The labor cost of erecting and handling but not operating this construction equipment is 0.4 per cent; making the total cost to the job for the use of plant 1.65 per cent of the total cost of the undertaking. On the basis of an annual volume of work amounting to \$3,640,000,000, the annual cost for construction plant would be about \$60,000,000.

The average cost of small tools is about 0.75 per cent of the total cost of the undertaking and on a similar basis would amount to \$27,300,000. The total annual cost of both construction plant and tools would be roughly \$90,000,000.

It is obvious that good judgment must be used in selecting and laying out the construction equipment required for the execution of any undertaking. It is not unusual to observe work on which the intelligent use of equipment would reduce labor costs appreciably after making allowance for the rental on the equipment. Possibly it is a more unusual occurrence, but it is far too common to observe work where the savings effected by the use of plant do not justify the amount of plant involved. More frequently still it happens that a proper amount of plant is in use but is not so arranged as to produce the best results. Observation indicates that the annual loss due to improper or improperly arranged equipment exceeds 10 per cent of the rental of equipment, or more than \$6,000,000.

All contractors are familiar with losses which occur in the use of small tools, and various means have been employed to reduce such losses, such as the refusal to supply tools to those trades which customarily supply their own tools; the charging against each individual of the value of the tool which he borrows from the store room, holding him responsible for its return; and maintaining a salvage corps whose duty is not only to look after all scattered material but also to check up tools which may be found lying around. The experience of one construction company indicated an annual loss of as high as 20 per cent of the value of the small tools which was eliminated by the vigilance of the salvage corps. Ten per cent would appear to be a conservative estimate of the preventable waste in small tools, or say \$3,000,000.

MISCELLANEOUS WASTE

Various miscellaneous forms of waste occur in the construction industry which are difficult of translation into concrete figures. Among these is bad management, which in a degree is responsible for all of the losses which have been previously dealt with, and, in addition, for other losses more out of the ordinary, such as excessive costs for material and labor, waste of material, errors in executing work, as well as errors of judgment which may result in the performance of the work at a loss both to contractor and owner.

Multiplication of effort on the part of the owner, architect, engineer and contractor. This consists in maintaining various sets of inspectors, material checkers, time keepers, etc., who are certainly not necessary on all work. Closer co-operation among owner, engineer and contractor should do away with a certain amount of this multiplication of effort. The contractor frequently needs no more supervision than the architect or engineer, and the contractor who requires more inspectors than are necessary to assist in the interpretation of the owner's, architect's or engineer's ideas should not be employed on the work.

CONCLUSION

To sum up, there is waste in various forms in the construction industry, some of which can be materially reduced by proper effort on the part of the contractor, the workmen, the owner and his architect or engineer. It is believed that the following figures represent roughly the annual amount of preventable waste with a volume of business equal to that of 1920:

Manner of letting contracts.....	\$16,000,000
Abnormal risk in the construction industry.....	21,000,000
Accidents to workmen.....	30,000,000
Restriction of output.....	36,000,000
Intermittence of employment.....	15,000,000
Labor turnover.....	8,000,000
Lack of proper cost accounting.....	4,000,000
Improper use of construction equipment and tools, .	9,000,000
Total.....	\$139,000,000

This amount is equivalent to 3.8 per cent of the total annual expenditure in construction work and is practically equal to the total annual net profits of the entire construction industry.

Rough as these figures are, it is believed that they err in being low rather than high.

With such a showing, the responsibility clearly devolves upon all engaged in the industry to exert themselves to eliminate the preventable waste. It can be done.

New York City.

Some Considerations on Fire Waste

Industry in General, and the Chemical Industry in Particular, Is in Need of a Fuller Appreciation of Fire Hazards and the Appalling Waste Due to Destruction by Fire—
Review of Possible Fire Hazards

BY NICHOLAS RICHARDSON
Research Engineer, Watertown Arsenal

OUR fire waste is enormous. Daily and hourly much of our wealth goes up in smoke. Our dwellings, factories, crops and forests are being destroyed at a rate which must cause every thoughtful person often to doubt our general intelligence. The daily accounts in the press of disastrous fires, the continual spectacle of fire engines dashing through the streets of our cities, the smoke of our forest fires, have become a national institution which would appear to be accepted with complacency, and it is impossible to believe that the public in general can have any true appreciation of how great and how serious a waste it all entails. A very large proportion of this waste is preventable and therefore unnecessary.

INSURANCE A TAX TO HELP THE FEW

There are some, doubtless jealously regarding themselves as responsible citizens, to whom the spectacle of a fire or the dramatic newspaper account of a conflagration is no more than a welcome diversion, and it is no exaggeration to say that there are many such. How often, when it is learned that "the loss was fully covered by insurance," is a feeling engendered that there has been practically no loss at all, and how many of us forget that insurance is simply a taxing of the many to help the few! We are all obliged for self-protection to indemnify the careless and the negligent.

When material is destroyed by fire it is gone, irretrievably lost, and the world is so much the poorer. When any useful thing is wasted we must inevitably pay more for that thing than we otherwise should, and every fire increases the burden of living.

We are speaking now of the actual waste of goods by fire, but it must also be remembered that there is an enormous consequential expenditure of money, time, energy and thought for fire-fighting and for protection against hazards which ought not to exist. Is not all this also waste?

The foregoing remarks are commonplace and trite. The appalling facts are repeatedly being published, and homilies on the lines of the above are reiterated in current trade and technical journals. The business man, while smoking a cigarette in an interval of business, reads such remarks with weariness, and closes the paper with a feeling of boredom, the while nonchalantly throwing his cigarette through the office window. The cigarette falling ignites an awning below; a blaze occurs; an alarm is rung; the firemen arrive; traffic is held up; the awning is destroyed, windows are broken and hundreds of dollars' worth of goods damaged.

The owner of the awning at once communicates with his insurance agent, and in a day or two he sees, not without satisfaction, a new awning beautifying his premises. And so trivialities of daily life go on.

Fire hazard is always present, and must be so under the conditions in which we live. Our very existence depends on slow oxidation and a large proportion of the substances which are necessary to our lives, particularly material necessary for our food, clothing and shelter, the fundamentals of existence, have so great an affinity for the oxygen of the atmosphere that it requires but a slight increase in temperature to start rapid combustion and the necessities of life are violently converted into different and useless compounds, and as far as we are concerned they are irretrievably wasted.

Such being the case, it would seem natural that every person would learn from the cradle that fire must be regarded as a vicious enemy and that continued heed and care must be given that uncontrolled fire shall not be allowed to start. But that it is not so is evident from the record of our fire waste. There is, however, some hope for the future. The increasing instruction of children in schools as to fire dangers, the training given to Boy Scouts and the institution of "clean up" and "fire prevention" periods will doubtless tell in a more careful and less wasteful generation. In the meantime, however, the waste goes on, as the following figures will show.

RECORDED FIRE LOSS NEARLY QUARTER MILLION YEARLY

The Actuarial Bureau of the National Board of Fire Underwriters lately published a table showing the recorded fire loss in the five-year period from 1915 to 1919. This table includes the losses on insured property only, and a large addition must be made to account for uninsured and unreported fires. It is important to note that forest fires are not included and it would be difficult to estimate in dollars the loss and waste due to the destruction of growing timber. The amount must be enormous, and the waste thus occasioned to one of our most important national resources is deplorable.

During the five-year period from 1915 to 1919 there was a recorded and insured waste of \$1,133,100,676. To this amount is added 25 per cent, which is a conservative estimate of the value of uninsured and unreported losses. The total thus reaches the staggering figure of \$1,416,375,000. The National Board of Fire Underwriters in publishing the figures points out that this amount if used instead of wasted would provide homes for a population exceeding that of the State of Connecticut. In the five-year period considered there has therefore been an annual fire waste to the amount of \$226,620,135 in recorded and insured fires.

The present five-year period promises to exceed this startling record. The waste during 1920 was considerably more than \$500,000,000, or double the average

annual waste of the five-year period considered. Nor is there much hope for a betterment this year. From January to June, 1921, the fire record stands at \$164,-926,300 and there appear no grounds for an expectation that the record for the coming half year will be low enough to bring the year's total to a figure at all favorable in comparison with the average of the past, enormous though that average is.

25 PER CENT ENTIRELY PREVENTABLE

In examining the table it will be seen that the losses with their causes are arranged in the order of their magnitude. The first and most striking fact is that 25 per cent of the total is due to causes which are entirely preventable, the remainder being classed as "partly preventable." Space will not permit of detailed

RECORDED FIRE LOSS DURING FIVE-YEAR PERIOD BETWEEN 1915 AND 1919		
Preventable Causes	Amount of Loss	Per Cent of Total
Matches and smoking.....	\$73,474,348	6.4
Defective chimneys and flues.....	56,650,915	5.0
Stoves, furnaces, boilers and their pipes.....	55,133,181	4.9
Sparks on roof.....	29,271,585	2.6
Petroleum and its products.....	25,910,434	2.3
Open lights.....	13,956,032	1.2
Hot ashes and coals, open fires.....	11,806,754	1.0
Gas, natural and artificial.....	10,203,330	0.9
Ignition of hot grease, oil, tar, wax and asphalt....	4,490,269	0.4
Rubbish.....	3,511,824	0.4
Steam and hot water pipes.....	1,851,434	0.2
Fireworks.....	1,499,854	0.2
Total.....	\$287,759,960	25.5
Partly Preventable Causes		
Unknown causes, probably largely preventable....	\$360,587,544	31.8
Exposure, including conflagrations.....	202,176,433	17.8
Electricity.....	84,086,471	7.4
Spontaneous combustion.....	49,702,886	4.4
Lightning.....	39,828,489	3.5
Sparks from machinery.....	31,862,424	2.8
Sparks from combustion.....	25,144,191	2.2
Incendiarism.....	21,596,965	1.9
Miscellaneous known causes.....	20,193,164	1.8
Explosions.....	10,162,149	0.9
Total.....	\$845,340,716	74.5
Total fire waste in five years.....	\$1,133,100,676	

analysis of these preventable causes, nor is an analysis necessary. Any intelligent man can see at a glance how simple and obvious the causes are.

Can any valid excuse be offered for waste caused by defective chimneys and flues, or fires caused by hot coals and ashes? It is sad to acknowledge that smoking is accountable for nearly 6½ per cent of the total; and the reformers who are now working to place tobacco under the ban along with liquor have in this an argument difficult to refute.

It may here be remarked that "exposure, including conflagrations," which accounts for nearly 18 per cent of the total waste, is one of the peculiarly vicious features of the causes of fire waste. It is here that the innocent suffer for the guilty and where one who employs all means to prevent fire may suffer disastrous losses owing to the neglect and carelessness of his neighbor.

"COMMON" HAZARDS

In the language of fire prevention, the potential causes of fire are classed as "common" and "special" hazards. Common hazards are those which are met with everywhere, and include the fire hazards of heating, lighting, power, disposal of rubbish and the like. It is very easy to learn how all common hazards may be safeguarded, and it can truthfully be said that any fire originating in a common hazard is evidence of neglect which may amount to criminality on the part of someone.

As shown in the table, common hazards are by far the greatest causes of fire waste, and it is in the common hazard class where there is the greatest field for improvement. The means for safeguarding all the common hazards have long been practically standardized, and ignorance can no longer be claimed as an excuse for fire waste arising from common hazard causes. The National Board of Fire Underwriters, the National Fire Protection Association and other organizations publish information covering all prevention methods for common hazards. Such information is available to all. Instruction given in schools and other institutions must place all this information at the disposal of everybody.

"SPECIAL" HAZARDS

In the field of special hazards there are problems of more interest to the technician and specialist, and there is still much opportunity for research. Special hazards are the potential causes of fire arising from the technique of manufacture, and practically every type of manufacturing has its peculiar and necessary special hazards. In this connection most of the credit for safeguarding innumerable manufacturing processes is due, not to the manufacturers themselves but to insurance interests, and not only the protection of special manufacturing processes but also the proper arrangement and conduct of industrial operations effectively to prevent or minimize possible fire waste frequently must be pointed out by insurance men.

To illustrate this line of thought, an example may be taken by considering the common course of events when a new factory—let us say, for example, a chocolate and candy factory—is started. The plant is designed by engineers in consultation with a candy-manufacturing specialist, and the plans are laid out for the most efficient and economical handling of material from raw stock to finished product. The type of construction may be of the best and the provisions for the safeguarding of common hazards may be above criticism. The plant is built and finished and production begins. The building machinery and stock represent a large capital outlay and the dread of loss by fire looms large, although the president of the concern himself "cannot see where a fire can possibly start." The plant, however, must be insured and a policy is written covering buildings, machinery and stock. Then comes the question of the rate to be paid, and the treasurer learns some things which may cause him many bad moments.

INSURANCE "REQUIREMENTS" APPAL THE MANUFACTURER

The insurance engineers inspect the plant and in due course a list of "requirements" arrives, only on the execution of which will a rate be made which appears to approach reasonableness according to the ideas of the treasurer. In the first place, the plant is not protected with automatic sprinklers, an omission which causes the rate to be several times as great as it otherwise might be. It is then discovered that there are no "cutoffs" of value, and for the first time the obvious fact is noted that if large values in stock and machinery are concentrated together without division walls which could stop or at least check the advance of fire, the chances of a large destruction resulting from a possible small fire are many times increased. The erection of dividing fire walls or "cutoffs" is strongly objected to by the production manager and it

is difficult to convince him that a small fire could completely stop his entire production for a long period and in a few moments wipe out all the saving which he could show by the elimination of fire walls or divisions.

It is then pointed out that raw stock or possibly finished goods of large value are stored in basements resting directly on the ground and no provision made for drainage of water, and in this case it probably will be impossible for the insurance engineer to convince the works manager that the expense of "skidding" or raising all stock from the floor is worth while, nor will he possibly be convinced until a small and perhaps insignificant fire occurs in some upper floor, and the water used in extinguishing the fire, flowing to the basement, damages the whole stock therein. The writer remembers a case where the actual fire loss was \$10; the water used in extinguishing the fire damaged goods to the extent of \$14,000, and an expenditure of a few dollars only in raising the stock from the basement floor would have saved it all.

COMMON PRACTICE TO TAKE A CHANCE

The special hazards of chocolate and candy making, then, receive the attention of the insurance engineer. It is found that the dry and hot rooms are made of wood, that cocoa grinding is carried on in an important part of the building without protection against explosions, that there are unprotected ducts between floors and many other special hazards not protected in any way. The managers blame the architect, the architect blames the production manager, they all damn the insurance companies, and the insurance engineer marvels at the ignorance and pigheadedness of some great executives! The matter ends in a "business" man's decision. It is calculated that it will be to immediate financial benefit to refrain from carrying out the requirements and to pay the larger rate. So things are left to chance. All may go well and no fire may occur; on the other hand, a fire may occur and the resultant loss and waste will inevitably be many times greater than would have been the case had the advice of the insurance interests been heeded. This simple scenario may appear to be highly colored, but every incident is founded on fact, as any insurance engineer can testify.

It is time that elimination of waste by fire be recognized as a duty by the large business interests and a more altruistic attitude assumed by those who deal with the material of the common wants of men. That a few may increase their riches by risking the resources of the world is a terrible wrong, but it is unfortunately a widespread custom.

CLOSE INVESTIGATION OF FIRE RISKS NEEDED IN CHEMICAL AND ALLIED INDUSTRIES

New production methods are continually being adopted in practically all types of manufacturing. Many of these methods may entail some fire risk and therefore a close investigation of all changes in manufacturing processes should be made before they are put into practice. In the so-called chemical and allied industries this is especially necessary. Of late years the great increase in the synthetic production of many substances has introduced many hazards into manufacturing which can be appreciated only by technical men of high training. Our chemists have as high skill as

any in the world and at the present time our colleges and technical schools are turning out young men equipped with scientific knowledge who willingly accept minor positions in chemical factories. There is an abundance of knowledge and ability to foresee and guard against possible dangers, but with it all too often the fire hazard situation is overlooked or wilfully neglected. The chemist who has conceived a process is too anxious to have his ideas pushed to fruition, and the production man is too eager to obtain a large and low cost output to permit any delay or additional expense which might be necessary to make the process actually safe. It is an unfortunate fact that highly gifted technical men are not always good business men, and on the other hand a good business man seldom has sufficient technical knowledge to appreciate the practical dangers which may accompany some brilliantly conceived technical process.

POTENTIAL RISKS OF FIRE IN CHEMICAL PLANTS

An outside person critically inspecting a large number of chemical and allied plants cannot but be impressed by the numbers of potential risks of fire waste which may appear to him self-evident. How often is dye grinding carried on in the same building and right in the midst of a stock of finished dyes, whose value may reach hundreds of thousands of dollars. Such stock can be rendered valueless, or in other words can be turned into waste by a comparatively slight accident. Again, how often is nitrating—a process always accompanied by the greatest danger—practiced in close proximity to valuable machinery and large amounts of flammable material. The writer has suffered contempt little short of insult from chemists and managers who are eminent in their line because he has pointed out possibilities of fire and explosion waste and suggested preventives which were obvious in their simplicity. And not a few times has the possibility suddenly changed to an actuality; and waste to a greater or lesser extent has followed.

LITTLE STUDY OF FIRE AND EXPLOSION DANGERS

The study of fire and explosion dangers in dye and other synthetic chemical factories has been made by very few. Indeed, no one who is not an experienced chemist is capable of tackling the subject with intelligence. There are of course a number of dangerous processes which today are so common in chemical manufacturing that the dangers incident to them are or by this time should be well known to all, but the attempts at "short cuts" and the continual introduction of the manufacture of new compounds may be accompanied by unexpected dangers.

The history of a case could be recited where an old and (in its own estimation) careful concern registered indignant surprise when it was suggested that its plant for making H acid represented considerable danger. The accident which followed not long after "surprised" a workman into the next world and the insurance companies to the tune of thousands of dollars.

The types of organic compounds which are synthetically manufactured are never very far removed from true explosives. Sometimes it takes but little to change innocuous material into a sensitive explosive.

It must of course be recognized that occasionally a manufacturer is unable to carry on his business were

he to protect himself against possible accident in a manner which is actually effective. Circumstances may be such that he is obliged to trust to chance that an accident will not occur. He probably considers that he is in fact properly protected by the insurance he carries, and from his own financial viewpoint it is possible that he is so protected. But when the accident occurs there is an addition to the world's waste for which somebody will certainly suffer. It may be argued that advance is made only by those who will take chances, but nothing can be considered as true progress if preventable waste is the accompaniment.

INVESTIGATIONS THAT SHOULD BE MADE

Attention has been drawn above to the fact that research and progress in fire prevention and the proper safeguarding of dangerous manufacturing processes have been initiated and to the largest extent carried on by insurance interests. This is proper and natural enough, but it is unfortunate in creating an impression among many that it is only a trick of fire underwriters to increase their profits. It would be well in many instances if the insurance features could be disregarded and fire prevention problems considered solely from their necessity in order to reduce waste. There are simple broad lines on which all new industrial propositions should be carefully investigated before they are put into any considerable operation. Such an investigation should examine into the following matters:

The nature of the raw stock to be used; its degree of combustibility and susceptibility to damage by heat, smoke and water; the safe storage of raw stock; the avoidance of concentration in one area in order that the smallest practical amount may be subject to damage by any one fire. The same of course applies even more to the storage of finished goods, these representing not only the material itself alone but also the labor and thought expended upon it. True fireproof construction of all manufacturing and storage buildings is naturally the most desirable in the majority of cases.

FIREPROOF BUILDING MAY BE IDEAL FURNACE

In this connection it must be remembered that fireproof construction does not mean that a building is composed only of non-combustible material, for although such a building will not burn it can very easily be destroyed by fire. It is understood that Mr. Edison discovered this fact by practical experience. It is remarkable, but nevertheless a fact, that many experienced business men cling to the delusion that if machinery and stock are housed in fireproof buildings no further anxiety need be felt as to fire. The absurdity of this is evident, since many a strictly fireproof building is so designed that it becomes an ideal furnace for the burning of combustible material.

In continuing the review of the possible fire conditions inherent in any proposed manufacturing enterprise, a close study of the separate and individual processes should be made. Any process producing dust and processes using volatile flammables will certainly be exposed to danger of explosion. Where such dangers are very great, such processes should be isolated. It is usually easy to arrange any dangerous process in such a way that the occurrence of an accident will entail only small waste, but it is essential that a recognition of the danger and adoption of precautions take place before an accident can occur.

An example of the great possibilities in the prevention of fire waste and loss by the scientific study of special hazards may be cited in the history of cotton mills. In the past cotton mills were particular sufferers from fire losses and were considered as a type of manufacturing to which fire was an inevitable concomitant. With the organization and development of the Factory Mutual Insurance Association honest efforts were made to improve conditions. The type of construction, the handling of stock, the peculiar fire risks incident to cotton picking, carding and spinning were made the careful study of trained engineers, and methods and means of annulling dangers were rapidly devised. Automatic sprinklers, together with efficient fire-fighting appliances, were brought into general use—in a word, the whole question of preventing fire waste was taken up carefully and systematically. The result is that cotton mills today have an excellent record as to fire waste, and fire losses of any magnitude due to the heavy special hazards of cotton manufacturing are almost unknown.

It would not be fair, however, to compare an old and standardized industry such as cotton manufacturing with so new and inexperienced an industry as synthetic dye making. The point, however, lies in the fact that if attention is given to fire prevention the fire waste due to special hazards in any industry will be enormously decreased.

NEW INDUSTRIES CREATE NEW HAZARDS

Our industrial growth has been great, and every year sees types of industries begun that are new to the country. Since this is a country of new things, it behooves us to have our eyes open to new dangers. It is superfluous to specify examples of new enterprises where grave dangers may be introduced unless the need of scientific fire prevention is recognized from the very beginning of operations. The phenomenal increase in the use of gasoline and fuel oil, necessitating the installation of storages for great stocks of these flammables right at the very doors of our industrial centers, is only one example. At this writing news comes of a fire where millions of gallons of oil have just been wasted and where had proper consideration been given to fire prevention in the isolation of units and the proper construction and diking of tanks, the waste of one of our most valuable and limited national products would have been immensely reduced, if not entirely prevented.

Nothing has been said of our waste of life by fire, but when it is emphasized that 20,000 persons meet death annually by fire, and meet death in the most terrible way imaginable, enough has been said on that point. It is horrible even to think of what death by fire means, and it is impossible even to estimate the economic loss in the waste of human life.

Enough has been said to justify an earnest plea for the more general recognition of the needlessness of our colossal fire waste. For the reproach of our fire waste owing to common hazard causes we are all to blame, and every one of us can help to reduce the national blot. As to the waste due to special industrial fire hazards its reduction lies with the heads of factories.

The protection of much of our national resources lies in their hands and setting aside selfish and present financial gains they should consider it a duty to the nation to see to it that preventable fire waste shall cease so far as they are concerned.

Location as a Factor in Eliminating Industrial Waste

The Main Factors to Be Considered in the Selection of Proper Location for Industrial Plants Are: The Influence Which a Proposed Industry Will Have on the Community, Raw Materials, Transportation, Labor Supply and Power

BY VICTOR V. KELSEY
Assistant Works Manager, Corning Glass Works

THE importance of the proper location of industries as a factor for the elimination of industrial waste is a point conceded by all, but is frequently overlooked until too late to make a change.

In selecting a location for an industry a number of important questions naturally arise which should be thoroughly answered before reaching a final decision for the plant site. To arrive satisfactorily at the correct answers it is necessary to make a careful analysis of all the major economic conditions. This duty falls to the lot of management, and if properly done it means the first step in overcoming industrial waste, 75 per cent of which is now attributed to inefficient management.

The committee of the American Engineering Council defines waste in industry as "that part of the material, time and human effort expended in production represented by the difference between the average attainment on one hand and the performance actually attained on the other." The sources and causes of waste are classified by them as follows:

1. Low production caused by faulty management of materials, plant equipment and men.
2. Interrupted production, caused by idle men, idle materials, idle plants and idle equipment.
3. Restricted production, intentionally caused by owners, management and labor.
4. Lost production, caused by ill health, physical defects and industrial accident.

To this list should be added the waste caused by locating plants in communities not properly adapted for them, resulting in high cost of production and sometimes ultimate failure, all of which must be paid for by the public.

The first charge of industrial managers is proper plant location. This factor satisfactorily taken care of is a step forward to success.

INFLUENCE WHICH A PROPOSED INDUSTRY WILL HAVE ON THE COMMUNITY TO BE CONSIDERED

Such necessary conditions to be met as raw materials, transportation, markets, labor supply, etc., are of no more importance than a full consideration of the influences prevalent in the community, in so far as they relate to industrial development and the influence which the proposed industry will have on the community. Any number of localities are seeking new factories and offer many attractive inducements. Frequently these inducements include a free tract of land in the section set aside for plant development. The industry moves in, becomes established, starts the manufacture of its product. Then the community wakes up to the fact that instead of having an asset it has a liability, for the reason that the fumes, dust or odors arising from the manufactur-

ing processes become obnoxious to the people of the community and they sometimes declare them a nuisance, which results in loss of production and thus creates an industrial waste.

The writer has in mind three large chemical industries which were improperly located for the reasons stated above.

The first of these three was very properly placed near its source of raw materials and later a town grew up practically surrounding the plant. The town builders in this instance were at fault, as the town could have been located at a sufficiently great distance from the plant to avoid the annoyance caused by the dust.

The second of these industries was located in a section of a town which was building up rapidly and the fumes from the sulphur compounds that were manufactured soon became a marked nuisance. The management was decidedly at fault in this instance, as it must have known that the odors from the plant would not be welcomed by the community.

The third industry selected a large site near a growing town, with a full knowledge on the part of the management that sooner or later its presence would not be cherished by the citizens of the town, and it so happened that the "city fathers," in their zealotry to promote industrial expansion, asked few if any questions as to the products to be manufactured other than that they were told the textile plants took a goodly portion of their finished wares. The odors from this plant and the fact that large quantities of explosive and flammable materials must be carried in stock create both a nuisance and a hazard to the community. Sooner or later someone will demand an investigation which may result in loss of production.

With proper care and foresight so-called undesirable chemical industries can select locations relative to towns or cities that will result beneficially to all concerned. This class of industries, as well as all others, owes much to the community in which they are located. They are an integral part of the community, no less so than the churches, schools, stores, theaters, etc. They must get the proper viewpoint in their relation to the community, and the converse of this must prove to be true, and when this is accomplished then a great deal of the prevailing industrial waste will cease.

SOURCE AND PERMANENCY OF RAW MATERIALS

The source and permanency of the raw materials is usually one of the most important controlling factors in deciding upon a location. A dependable supply of the proper quality of raw products must be assured.

I have in mind a plant built in the East, designed to reclaim a certain waste material produced by the large brass mills in the same general territory. The plant

was located near the source of its raw product and was operated profitably. The management decided that the same type of plant, though of smaller capacity, located in a city in the Middle West would also prosper. They failed to ascertain the amount which could be had of their raw product nor did they inquire with sufficient care into the location. As a result it proved to be, first, so far from their factory that they could not afford to pay the heavy transportation charges, and second, the amount of raw material available was not sufficiently great to permit operating their plant to capacity even though it could be economically assembled. This particular plant was a financial failure from the day it was completed and the whole blame lies at the door of the management in failing to make a thorough and proper analysis of their most important raw material.

TRANSPORTATION FACILITIES

A number of large and important industries operating today are feeling the pinch of freight rates on their raw materials. When the present sites were selected the raw materials were, in most instances, relatively close at hand. These sources have, in a great many cases, become exhausted and the industries are now forced to go great distances for them, which means competition with plants making similar products located near their basic materials, and competition grows keener each year.

The markets for the finished product is a factor of prime importance, but inasmuch as they are usually scattered, the relative proximity to the producing factory is not, as a rule, of as great importance as the source and proximity of raw materials. The carrying charges on finished articles, while generally higher than on raw products, do not aggregate as much, in most instances, as they are shipped in smaller quantities to the ultimate consumer.

Transportation facilities are important from the standpoint of permitting, in most cases, the assembling of the raw materials and the distribution of the finished ware in the most economical way.

If possible, a location should be selected which permits the raw materials to be assembled by the shortest hauls, thereby taking advantage of minimum freight rates and the distribution of finished articles over the most direct routes.

LABOR SUPPLY

The question of labor supply is one that receives more attention than perhaps any of the others in deciding upon a proper location for a factory. Some managers contend that the small community offers the best inducement for contented labor and minimum labor turnover, and while the supply is not so great or so flexible as in the larger centers, production can be maintained at higher levels and accomplished at lower costs.

In my opinion the smaller communities offer the best inducements for labor providing certain essential factors are carried out so as to make the labor contented, such as suitable homes built in attractive designs and on lots sufficiently large to provide space for lawns and vegetable gardens.

The plan of building a string of company houses all of the same design does not make contented labor. The quality and design must be such that the workman will have a desire to purchase, and arrangements must be effected to enable him to make the purchase by paying a small initial sum, followed by monthly payments within the limits of his earnings.

Along with the housing development must be provided recreational centers such as baseball fields, tennis courts, moving picture theaters, good schools and churches. Conditions of this kind will obtain and hold highly skilled workmen as well as unskilled workmen.

Industrial communities built up in this manner permit the workmen to have a voice in civic affairs and thus intensifies their interest in their work and in their homes.

POWER SUPPLY

The experiences of the coal shortage a little more than a year ago are fresh in the minds of all industrial managers. Never before has the matter of power been so forcibly brought to the front as a tremendous factor in production. As a result of this experience proposed industries consider most carefully locations in their relation to adequate coal supplies and other supplies of power. Hydro-electric developments are now being considered which heretofore were thought to be out of the question as requiring too much money for their installation. This type of power source will make remarkable increases during the next few years. Big central generating stations designed to furnish power to a number of plants in their territory will be built up in greater numbers in the near future. Power-generating units, though more costly in design than in past years, will be installed in increasing numbers on account of their greater efficiency, thus tending to lower the cost of power. The essential point is the nearness to the coal mine of dependable quantity and quality, except sites that offer power from hydro-electric stations.

CLIMATIC AND OTHER FACTORS TO BE CONSIDERED IN THE SELECTION OF POWER SITES

The size and topography of the proposed site are important from the standpoint of permitting expansion and affecting the cost of building.

Climatic conditions have a direct bearing on the speed with which labor accomplishes its work and on the cost of living. The colder climates require more and heavier clothes and a greater amount of fuel for the winter months than would have to be provided in a warmer climate, thus necessitating somewhat higher wages.

The advertising value of a plant site may or may not be an economic factor. It is believed that the public can be induced to purchase wares of merit by proper advertising and that the home of the manufactured article has very little effect in an advertising way.

Decentralization of industry has its advocates, and not without reason. There is greater flexibility to be had, both by the management and by labor, in communities that are not crowded due to a number of big industries being situated close to one another.

Sociological conditions are far better in the less congested districts and, as a rule, there are fewer laws to contend with which tend to stifle industry.

It is believed that industrial engineers in general will do well to prepare a list of certain conditions to be met in selecting the proper plant location.

A great many data are now available from numerous sources, but these have not been compiled in a systematic and orderly way. Such a compilation would be of great help to chambers of commerce, industrial agents and others interested in recommending sites for industries. The right kind of information would stop further industrial waste due to improper plant location.

Corning, N. Y.

Reduction of Waste Through Accident Prevention

The Chemical Industry in Many of Its Branches Is in the Development or Quasi-Experimental Stage in This Country—It Is Therefore Important That Its Industrial Accidents Should Be Carefully Analyzed

BY L. A. DEBLOIS

Manager, Safety Section, E. I. du Pont de Nemours & Co.

IF THE chemical industry of the United States is to compete successfully with the longer experience and the cheaper labor of European countries, it is admitted that the highest operating efficiencies must be attained and the greatest economies effected; in a word, waste of time, labor, power and material must be coaxed down to the irreducible minimum, without sacrifice of quantity production and with constantly improved quality. To achieve this irreducible minimum it behooves us to subject every possible source of waste to the closest scrutiny and to consider well before it is rejected as unavoidable or too trivial for our attention. In fact, the terms unavoidable, trivial and "inherent to the industry" should be regarded with suspicion, as possible spurious currency, until their true value is proved.

ACCIDENT PREVENTION A MATTER OF UTMOST CONCERN TO THE CHEMICAL INDUSTRY

No one denies that accidents cost money, though many reckon their cost only in terms of liability insurance premiums. Their bearing on the available man power of the country was emphasized during war-time labor shortage, but in these times of glutted labor markets it has lost much of its former significance, and yet accident prevention is, or should be, today a matter of utmost concern to the chemical industry. It is not, however, that the Europeans have progressed farther in accident prevention measures than ourselves, but that to overcome other of our competitive disadvantages we should excel them in this field at least and profit by the economies that will result.

IMPEDIMENTS TO ACCIDENT PREVENTION

There have been two great impediments in the onward march of what accident prevention enthusiasts are pleased to call "universal safety": First, a lament-

able failure to measure the far-reaching consequences of the average industrial accident, and second, the sublime and childlike faith of the human race in its own interpretation of what is "luck," "chance" or "Providence" as applied to accident occurrence. The first has led to an indifference to accidents which appeared of minor importance at first sight, but which were actually of profound significance in their bearing on industrial conditions; the second has persuaded us that many accidents are unavoidable or are caused by an inherent hazard or are mere chance occurrences when quite the contrary is true.

Most of us are inclined to regard accidental injuries as merely affecting the health and prosperity of the injured person and his or her immediate dependents, or, when liability for the accident is involved, the possible expense and annoyance to—in the case of industrial accidents—the employer. Under this point of view the accident with its train of consequences is commonly regarded as a complete episode, disagreeable, happening rather unexpectedly and not closely associated with the normal efficiency and routine of the industry in which it occurs. This is the everyday, every man point of view; but of late there has been developed by safety engineers a notably broader conception of the situation which promises to exert a powerful influence on the detection and reduction of industrial waste and inefficiency.

ELIMINATION OF CIRCUMSTANCES CONTRIBUTORY TO ACCIDENTS LEADS TO INCREASED EFFICIENCY

The new conception regards the nature and extent of injury as relatively unimportant, except of course for its humane aspects and in so far as it affects the cost of compensation. In fact, it regards it as being largely fortuitous: a man may be slightly injured or he may be killed under almost identical conditions. The impor-

tant matter is the train of circumstances that led up to the accident causing the injury. This can be made clearer by selecting an example. Let us assume that an elderly employee has been injured by a fall while in transit between buildings. Relatively the extent of his injury makes little difference. Investigation, however, reveals that he followed the usual route taken by the other employees and that there was ice on this path. Investigation further shows that other employees passing that way slipped but were agile enough to avoid a fall; or walked more cautiously; or went around the icy place. Whether they slipped, or slowed up, or detoured, their transit between buildings took an appreciably longer time than if there had been no ice there. By stop-watch the trip took four and one-half minutes instead of the normal four minutes. The ice was momentarily lowering their efficiency $12\frac{1}{2}$ per cent. This was the real lesson in the accident; the injury to the elderly employee was not a mere unconnected episode, but a warning of the existence of conditions leading to inefficiency. We remove the ice, then, not alone to prevent accidents but also to allow our employees to proceed on their way without loss of time—loss perhaps insignificant in each individual case, but in the aggregate worthy of our attention.

ELIMINATION OF ACCIDENTS BY IMPROVING THE EQUIPMENT

We may select as another illustration the operation of a battery of power-driven presses into which the raw material is fed manually by the operators. Three of these men have had their fingers caught by the descending dies and amputated. We may provide guards to prevent these accidents or we may adopt an automatic feeding device. The latter is selected and applied, the actual speed of the machines remaining unchanged. A month's trial demonstrates the fact that not only have we eliminated the accidents but we have increased the machine output 15 per cent. This latter result was somewhat unexpected and at first we are inclined to attribute it to the saving of time formerly lost through injury. That we have saved this is true, but it is not nearly enough to account for the increased output. Finally we reach the conclusion that the injuries were, after all, only the result of inefficient conditions of operation, quite unrecognized by us at the time, and that when they were eliminated the inefficiencies were eliminated also, unconsciously but effectively. Between the two was a subtle but definite relation. We conclude that inefficiency produces accidents occasionally, near-accidents frequently, and waste continually.

PROBABILITIES OF ACCIDENT OCCURRENCES

And now concerning the "providential" side of accidents. A close study of almost any single case invariably reveals a considerable number of circumstances contributory to the accident, but so inextricably interwoven with what we may call the primary injury causation (the act that brought about the injury) as to be in reality co-operative rather than contributory. The simultaneous occurrence of each of these contributory circumstances was essential to the occurrence of the accident, although all varied in their relative importance. Out of such a study we come quite naturally to the conclusion that a certain accident will always take place when all factors necessary to it occur simultaneously. It then becomes only a question of their simultaneous occurrence. If one factor, or contributory

circumstance, has a probability of occurrence of one in ten, and another has a probability of one in one hundred and the accident itself requires the simultaneous occurrence of both, it will occur inevitably once in one thousand times. There is nothing "providential" in this, no element of chance or luck any more than in the application of a match to a keg of gunpowder, and the sooner we lay aside such supposition the faster we will advance along the road to universal safety.

FOREMEN'S PART IN PREVENTING ACCIDENTS

The injured workman is very generally blamed for 60 to 75 per cent of the accidents. Undoubtedly he might have done something in most cases that would have prevented the accident from happening, might have exercised a little more care or forethought. But the important question for the employer to answer is what could he, the employer, have done. It is his productive efficiency and plant morale that are suffering by accidents, and to a degree far out of proportion to the mere injury. To whine about the responsibility of the workman is not mending matters. What kind of supervision are he and his foreman maintaining that injuries are allowed to occur at all? Are these foremen not part and parcel of his staff and subject to his influence? Injuries mean waste, and if this sort of waste is permitted by them, why not other sorts?

WASTE AND INEFFICIENCY PRECEDE ACCIDENTS

Probably the most frequent variety of injury occurring at all chemical plants is to the eyes from the entrance of foreign particles, often of acid or caustic. These accidents are commonly attributed to the failure of employees to wear the protective goggles that the plant provides for their use. Reasonably satisfactory goggles for practically every purpose are now obtainable and once provided it is squarely up to the manager of the plant and his staff, including the foremen, to see that they are worn. The usual excuse is "but my men won't wear them; they say—," etc. What nonsense! Would the management tolerate for an instant their refusal to mix or handle the raw materials or finished product in the way specified? The fault lies with the management, which is half-hearted in its insistence that goggles shall be worn and is inclined to blame the men for accidents which happen when they are not worn. It is absolutely within the power of any capable foreman to maintain the proper use of goggles, provided he has the expressed support of the plant manager.

But there is another angle to all this. It is quite proper that the eyes should be protected from the entrance of drops of acid and particles of caustic, but what are such materials as acid and caustic doing outside their proper pipe-lines, containers, etc.? These materials are valuable, and though the tiny drop or particle in question has an infinitesimal value, it was not the only drop that fell or particle that flew. Examination may show that considerable acid got away through the leaky gasket before any accident occurred or that considerable caustic was regularly wasted by the clumsy method of breaking up the solid caustic with a pick. If tanks are leaking, if repair men are not draining pipe-lines before breaking joints, if valve-gland packing is blowing out, if there are loose ingredients on floors and platforms, if mixing tanks are overflowing or splashing, if there is dust in suspension or dense fumes are liberated, then waste and inefficiency

are at work and accidents, the inevitable warning of the existence of such conditions, are taking place. The use of goggles will protect the eyes and save a man from total blindness—as it has done in hundreds of authenticated cases—but it will not greatly decrease industrial waste or inefficiency.

FALLACY OF "UNAVOIDABLE" ACCIDENTS

Not only are satisfactory goggles obtainable, but special protective clothing, including gloves, helmets, aprons, boots, safety carboy carriers which permit one man to do safely the work of two, carboy inclinators, safety acid jugs, sample bottle carriers and other devices. And yet with all the improved protective appliances, disabling and distressing accidents from acid and caustic continue to occur by hundreds, and many are classed by those who are themselves directly responsible for their occurrence as "unavoidable" or due to "inherent risk of the business."

There are two major classes into which these accidents may be divided—operating accidents and repairs accidents. Both classes may be diminished by better supervision in the operating field and by better supervision in the drafting and design departments. Many a careful repair man suffers an injury as the indirect result of parsimonious provision of inadequate space for routine and periodic repairs or the failure of the design engineer to give serious consideration to the need of such repairs—repairs as important and as inevitable on a chemical plant as the operation of the plant itself. Many an operator is injured as result of this same want of forethought, imagination or operating familiarity on the part of the design engineer or draftsman, who has utterly failed to consider matters of accessibility, adjustments, cleaning, oiling, etc. Behind them all, and properly sharing a proportion of the liability, is the manufacturer of machinery who, in order "to meet competition" or because "there is no demand from trade" fails properly to guard his product or provide for safe adjustments and repairs.

Take, for example, the common filter press. A few types are provided with gear and pinion or worm and gear setting-up devices, but the majority depend on the archaic—or at least Archimedean—bar and screw. It is not an uncommon experience in a chemical plant to see four or five men straining on these heavy bars, which are apt to slip from their sockets when rotated below the horizontal. It is safe to say that hundreds of men have had their feet crushed, legs broken, hands smashed or have been ruptured in this way. With a geared setting-up device, one man or at the most two men can do the work of four—and with safety.

SUPERVISION FOR SAFETY NEEDED IN THE PURCHASE OF EQUIPMENT

It is evident, then, that supervision for safety in the purchase of equipment is as important as supervision in design. Guards for exposed gearing are frequently supplied only as "extras," sawguards do not come with circular saws, essential quick-stopping devices are not given gratis with mixing rolls and calenders, and belt-shifters are not generally provided with an automatic locking device. The general design of the equipment should be scrutinized. The square-head jointer is still on the market. Some years ago one of the leading pump manufacturers turned out a plunger-type boiler feed-pump that was admirably adapted for cutting off the fingers of power-house engineers—and did its work

cleanly and efficiently—and only recently we encountered a boiler blow-off valve made by a reputable manufacturer so arranged that the bolts which held down the bonnet could come off while blowing down the boiler, and in fact did so. One wonders sometimes how much thought the manufacturers give the accident prevention question nowadays!

PREVENTION OF ACCIDENTS DURING REPAIR WORK

There is no doubt that the matter of plant repairs is an important one from the viewpoint of accident possibilities, particularly where there is a high degree of hazard in the materials of production. All too frequently there is no definite rule laid down by the management as to the relative responsibility of the operating foreman and the repairs foreman, and in default of this they are at loggerheads. The operating foreman should be the one man intimately familiar with the peculiar hazards attached to the matters under his immediate charge and should be charged with the general safety of repair gangs at work in his area, not to the extent of interfering with individuals but as advisory to their foreman. A recent serious accident involving three men overcome by fumes while making repairs inside a tank would have been avoided had the repairs foreman warned the house foreman of his intentions.

Also the repairs foreman, for his part, should not accept with implicit faith statements that all tanks are clear of fumes, that valves are closed, that pipes have been drained and are free from pressure, that switches are open and electric lines are dead, that "no one's going to open that valve, or start the motor, or throw the clutch." For the protection of his men he must quietly assure himself of these things and place padlocks, warning signs or blocking where they are necessary, and in doing so he must not take risks to which he would not subject his own men. There are also the after-accident precautionary measures to be attended to—the goggles and rubber gloves, the gas masks and life-lines, the bucket of water at hand in case of an acid or caustic splash, the location of the nearest water-shower and the condition of exits in case of a flash-fire or explosion. All such matters require careful supervision and constant drilling of foremen, but results will be found to pay for themselves. We should remember that the repairs foreman is rather an important factor in plant operation.

SAFETY BOOSTERS' CLUBS

The photograph heading page 403 shows the mechanical department of the Repauno Works of the du Pont company grouped beneath a sign which reads: "Something to Crow About: 590 Days Without Accident; Average Number of Men for the Year—160."

They finally completed 776 days without a single lost-time accident, though the department contained practically all the repairmen of the plant. This shows what can be done. And it is indeed amazing how the spirit of accident prevention, once awakened in foremen and men, does not die. The foreman of an average force of 643 construction men formed a "Safety Boosters Club" with the motto "Ninety Days or Bust." They "busted" twice, but finally reached their goal in the face of a 67 per cent labor turnover. In the whole period of 305 days there were only five accidents, an aggregate loss of 168 hours and a total cost of \$6. One combined explosives and acid plant, averaging about 250 men, has recently accomplished an unbroken record of fifteen months without an injury (five years ago

it averaged forty-eight lost-time injuries a year) and now seriously declares its intention of establishing a five-year record of freedom from accidents. Surely such men as these have lost all confidence in "luck" and have set up determination in its place!

PREVENTION OF ACCIDENT FROM INDUSTRIAL POISONING

In some branches of the chemical industry industrial poisoning from the ingredients or finished product introduces a special hazard even greater than that of injury by accident. This is particularly true of the dye industry, in which the possibilities of severe poisoning under careless methods of manufacture are legion. Associated with these are special hazards of explosion from excess pressure brought on by chemical reaction, explosions by virtue of rapid chemical decomposition, dust explosions, fume explosions and flash fires. Often the small-scale chemical manufacturer, the experimenter or the byproduct tyro discovers this to his cost and loss. The larger manufacturer, who has learned lessons from his earlier experiences, develops his processes through the laboratory stage, through the "semi-works scale" to the final full-scale equipment, which is itself for a long time changed and improved, but always with an eye open to accident and poisoning possibilities. Careful chemical supervision is of course necessary, but also careful safety and medical supervision. Production foremen and supervisors must not concern themselves solely with matters of quantity and quality, but must be constantly impressed by the management with the almost paramount considerations of safety to life and health. They must be made to feel that these matters cannot be left solely in the hands of the safety inspector and plant doctor. They must realize their own responsibility and accountability.

PERSONAL CLEANLINESS

Personal cleanliness on the part of plant employees is the *sine qua non* of the control of industrial poisoning, and it must be continually checked. To provide the facilities is not sufficient; their use must be encouraged and, if necessary, enforced. With this must go constant medical supervision, not of the variety that waits for patients to arrive with its feet upon the therapeutical desk, but the sort that goes forth, sees the men at their work, calls them by name and acquires their confidence. These, however, are prophylactic rather than curative measures. Poisoning may still occur and yield only to radical changes in equipment or methods. "But think of the expense—we have no money for changes!" Nor have you money to pay sick labor that is non-productive, to pay hospital bills, to pay funeral expenses and compensation for dependents. "Yes, but we don't pay for those, the insurance company does that." Quite so, but what do you pay the insurance company—1 per cent of your payroll, or 2 or possibly 4? In 1920 the du Pont company took care of its injured men on a more liberal scale than provided for by the state compensation acts at a cost of about 72c. per \$100 of payroll, which included medical, surgical and hospital costs and salaries of safety men engaged in compensation and settlement work. The estimated saving through self-insurance and accident reduction was sufficient to pay for all accident prevention work, both structural and educational, the salaries of safety departments at the plants and in the main office, and leave a net balance of 64 per cent as profit on the year's work.

BENEFICIAL RESULTS OF ACCIDENT PREVENTION

In the past ten years 75 per cent decrease in the severity of accidents has been attained in the plants of the du Pont company. To what extent this has effected productive efficiency it would be impossible to say. It has doubtless had its effect; though no well-defined line can be drawn between industrial waste and waste by accidents. It will, however, be of some interest to the readers of CHEMICAL & METALLURGICAL ENGINEERING to

INDUSTRIAL MALADY CURVES, DYE WORKS E. I. DU PONT DE NEMOURS & CO.

note a corresponding effect in the case of industrial poisons.

Coincident with the changes in equipment and methods in the manufacture of trinitrotoluol—one of the first industrial poisons encountered by the du Pont company—the following results took place:

Per 1,000,000 Lb. Handled in Manufacture		
Year	No. of Cases	Hours Lost From Poisoning
1914	11.	391
1918	0.2	11

And among the more varied ingredients and products of the dye works, the time lost on account of industrial poisoning decreased in 1920 39 per cent as against 1919; while the production in pounds, by virtue of changes, improved methods, etc., increased 47 per cent, giving in one year a net decrease of 58 per cent in number of days lost per unit of production.

Whether accident prevention and disease prevention promote productive efficiency or more efficient methods reduce accidents and poisoning is immaterial, so long as one recognizes the inseparable relationship that exists between them.

Wilmington, Del.

Responsibility of Owners in Waste Elimination

The owners of industry, through the banking function or otherwise, share in the responsibility for eliminating waste in industry. They have the duty particularly of assisting in stabilizing production. Carrying out such a policy is peculiarly the banker's interest. This is the conclusion reached by the Committee on Elimination of Waste in Industry of the Federated American Engineering Societies as stated in the summary of its report, July, 1921.

While it is true that balance sheets and income statements are gages of the degree of success of a business, it is evident from the assay of waste that these statements often do not reveal all or even the greater part of the facts regarding production. Certain banks have special industrial staffs to give service to their customers and to study industrial questions more closely. It may not be long before such things as good management methods are universally recognized as commercial assets.

Elimination of Waste in Industry Due to Poor Lighting

Industrial Accidents and Resulting Wastes of Man Power as Well as Costly Losses of Time, Materials and Production Can Often Be Avoided by the Installation and Proper Maintenance of Adequate Illumination

By WARD HARRISON

Illuminating Engineer, National Lamp Works

A CHEMICAL plant is a conspicuous example of an industry in which a large proportion of the work is necessarily carried on throughout the twenty-four hours. Consequently dependence must be placed upon artificial illumination for fully one-half of the time. More than this, many of the plants connected with the industry are so constructed that there is very little window space in proportion to the total floor area. In order to avoid an atmosphere of gloom and of dark areas where unseen dangers may lurk, and to keep such a plant clean and orderly, it may be necessary to use artificial light during the greater part of the day. As a rule a high level of artificial illumination over the large areas is not necessary, because the work does not involve fine discrimination of detail except at the gages, hydrometers, etc., where special lighting is usually provided. On the other hand, it is desirable to provide at least a moderate amount of illumination throughout the plant for the reasons mentioned above, and particularly in order to protect the workmen from accidents.

The opinion is often expressed by the layman that a greater amount of artificial light is used than necessary. Frequently he believes there is as much illumination in a brightly lighted room as there is in daylight out of doors. The facts are, however, that out of doors one may measure 500 to 1,000 or even 5,000 units of light. Indoors near the windows perhaps 100 units and less than 10 units anywhere is scarcely considered a good working light in the daytime. Often the night illumination in the same plants is around 0.1 of one unit of light (or 0.1 foot-candle as it is called). From 3 to 6 foot-candles is not too much for the general illumination of a chemical plant.

Accident hazard is particularly great in dimly lighted chemical plants. Obstacles may lie on the floor unseen until someone stumbles and is injured. An acid drip may go unnoticed, or the light may be so dim that the label on a dangerous chemical cannot be distinguished. The proverbial dark corner, however, does not exist in the case of a well-planned lighting installation in an interior with light colored walls and ceilings. An effective means of keeping corners clean and empty is to paint them white.

INDUSTRIAL ACCIDENTS CAUSED BY POOR LIGHTING

The largest item of waste in industry of which we have definite knowledge is the waste of man power due to accidents; and the chemical and steel industries are no exception in this respect. Regarding the relation of waste and accidents one can do no better than to quote directly from an article¹ by R. E. Simpson of the Travelers Insurance Co. "It has been definitely

established that ten years ago approximately 24 per cent of our industrial accidents were caused by poor lighting. In the intervening decade much progress has been made in the art of illumination and in promoting the safety of workers, with the result that this percentage has been considerably reduced. . . . If we admit that 15 per cent of our industrial accidents are due to the misuse of light sources what does this represent in financial and economic loss? . . .

"Our conception of the total economic loss that the foregoing figures involve will depend largely upon the unit costs with which they are associated. If we con-

FIG. 1. AN EFFECTIVE MEANS OF KEEPING CORNERS CLEAN

servatively estimate \$20 as the average weekly wage and assume that \$20 per week is needed in addition to cover medical attendance, hospital charges, loss in production, insurance and the various other items that enter the cost of an accident, we find the total annual cost, in round figures, approximates \$2,000,000,000, the part chargeable to poor lighting therefore being about \$300,000,000. This is a sum in excess of our yearly industrial-lighting bill, and hence we see that the misuse and inadequate use of lighting facilities in industry cost more than the light itself."

WASTES OF TIME AND PRODUCTION

The preface to the Wisconsin Industrial Lighting Code, in explaining why the state is concerned in the regulation of factory lighting, also discusses the economic advantages of good lighting as follows: "Finally, inadequate illumination decreases the production of the industries of the state, and to that extent the wealth of its people. Factory managers who have installed improved illumination are unanimous in the conviction

¹I. E. S. Transactions, vol. 15, No. 8.

that better lighting increases production and decreases spoilage."

Waste of time due to lack of supervision and discipline is also characteristic of dimly lighted areas. In such places a workman will take advantage of the opportunity which permits him to sit unnoticed in some dark corner, smoking or dozing for a while when in the meantime some important process is carried too far; in a well-lighted room such a scheme would not even suggest itself. It is a well-known fact that workmen are more contented in an orderly, well-lighted plant, and that contented workmen do more work and are more careful in their work. Order and neatness are much easier to maintain when there is sufficient light.

WASTES OF MATERIALS

A large item of waste in the chemical industry is the waste due to spoilage of entire batches of material. This is often caused by the incorrect reading of thermometers, hydrometers or gages traceable to lack of light. In plants that have a poor general lighting system and even in plants that have good general lighting, a special light is usually provided for reading gages. Bare lamps or poorly shaded lamps giving rise to direct glare should not be used for this purpose, and care should be exercised to place the lamp and reflector at such a height as to avoid reflected glare or "specular reflection" from the lamp on the gage.

FIG. 2. ILLUMINATION OF A GAGE GLASS

Another common cause of spoilage of batches is incorrect judgment of material, which may also be due to lack of light or to distortion of color. In order to avoid spoilage of batches due to color distortion, the so-called daylight lamps may be used. These lamps are particularly desirable in chemical laboratories and sample testing rooms and in fact wherever color discrimination is necessary. There are also devices on the market which reproduce with even greater exactness almost any quality of daylight desired, such as north skylight or noon sunlight. These are for use where a high degree of accuracy in color matching is necessary.

PRODUCTION AND LIGHTING COSTS

It may be of interest also to note briefly the results of some tests which have been conducted in order to determine the relation of lighting to production. In all of the efficiency tests conducted to date, the highest level of illumination investigated has invariably shown the greatest production and the greatest economy. In fact, in the range considered the relation of decreased production costs to total lighting costs is of the order of 10 to 1. Four such tests which were conducted in Chicago industrial plants under the supervision of W. A. Durgin show increases in production of 10 to 20 per cent resulting from better lighting.

During the last decade the trend of practically all manufacturing costs except the cost of light has been upward. In terms of other manufacturing costs, light now costs only one-tenth of what it did ten years ago. The cost of lighting per unit today is less than 3 per

FIG. 3. RLM STANDARD DOME REFLECTOR

cent of what it was in the days of the tallow candle. This means that where a number of years ago the cost of light prohibited the manufacturer from using more than a certain small amount, necessary for actual vision, he can now afford to use many times that amount of light, in order to carry on his manufacturing operations most economically.

EQUIPMENT FOR PROPER LIGHTING OF CHEMICAL PLANTS

A few practical suggestions as to the proper lighting for such plants as are typical of the chemical industry might be useful to those who are interested in installing a lighting system which will assist in establishing the greatest economy in the working of the plant.

As has been previously mentioned, a general lighting system is desirable, supplemented by local lighting for work requiring fine discrimination of detail. For the general illumination of the ordinary processes in this industry, from 3 to 6 foot-candles of illumination should be supplied. A type of lighting equipment which has a wide application is a porcelain-enameled steel reflector. A great variety of such reflectors have been used for industrial lighting, but some time ago, through the co-operation of the principal manufacturers of steel reflectors and the engineers of the lamp

FIG. 4. VAPOR-PROOF UNIT

manufacturers, specifications were drawn up for a standard porcelain-enameled steel dome reflector which embodied the advantages of the numerous older types and which omitted many of their defects. The specifications for this design have been issued by the research laboratories of the General Electric Co., and are

known as Reflector and Lamp Manufacturers (abbreviated RLM) Standard Specifications. Reflectors which comply with these specifications bear a statement to that effect in the form of a certificate of Inspection Service over the signature of the Electrical Testing Laboratories of New York City, which has been retained to conduct such periodical inspections and tests as will insure the uniform maintenance of the high quality prescribed in the specifications.

In order to reduce glare and glaring reflections, and to get better diffusion of the light, bowl enameled

FIG. 5. FOOT-CANDLE METER

lamps are preferable for use in RLM standard dome reflectors, except when the units are hung at a considerable mounting height—for instance, at least 18 or 20 ft.

In chemical plants it is often necessary to protect the electrical connections from acid fumes and flammable vapors. Vapor-proof units of rigid construction, able to withstand atmospheric conditions, have been designed for such locations.

MAINTENANCE OF ADEQUATE ILLUMINATION

Proper maintenance of a lighting system is a matter of great importance. In plants connected with the chemical or steel industries there is usually more or less smoke and dust in the air and the lighting system is particularly likely to deteriorate from this cause. Dirty reflectors, walls and ceilings darkened by smoke and dust, blackened lamps left in service as long as they continued to burn, empty sockets, unobserved burnouts, and replacements with lamps of wrong size or improper voltage rating are prime causes of inadequate illumination.

There are two methods by which the maintenance of any selected value of illumination can be assured: First, by allowing for an enormous depreciation in the light and consequently using much larger lamps than would ordinarily be considered necessary; and second, by maintaining the system properly and allowing for reasonable depreciation. The second, more generally practical, method involves: (1) The use of a depreciation factor, or factor of safety, in the original design of the system to insure adequate illumination when the system has depreciated a normal amount. (2) The cleaning of lighting units at frequent regular intervals. (3) The replacement of lamps which have become blackened in service by abnormally long life. (4) The use of lamps of the correct voltage rating for all replacements. (5) The refinishing of ceilings and walls at reasonable intervals.

How large an amount should be added to the intensity considered adequate, or, what amounts to the same thing, by how large a factor the intensity considered adequate should be multiplied to insure proper illumination at all times, depends upon the specific conditions surrounding any particular installation. In general, when installed in relatively favorable locations, open-reflector units show a depreciation which ranges from 10 to 25 per cent in four weeks time. Where excessive smoke and dust are the rule, the depreciation over the same period may be as high as 40 per cent. The depreciation of ceilings and walls depends not only upon the characteristics of the location—i.e., whether clean or dirty—but upon their original color as well.

USE OF THE FOOT-CANDLE METER

A device has recently been developed which will be found extremely useful in the proper maintenance of a lighting installation. This device is known as a foot-candle meter, for it measures the illumination at the work directly in terms of foot-candles. The instrument is shown in Fig. 5. With it the illumination can be read directly from the scale without computations or adjustments. In one large establishment where the superintendent uses a foot-candle meter systematically as a check on his maintenance department, readings of illumination intensity are taken at regular intervals at fixed stations throughout the plant. These readings are recorded in such a way that the successive readings are readily comparable. When any inconsistency appears in the records, an investigation is made and the proper remedy applied. The illumination in the offices

FIG. 6. CHEMICAL LABORATORY ILLUMINATED BY MEANS OF BOWL ENAMELED LAMPS IN DOME STEEL REFLECTORS, HAVING AN UPPER SECTION OF GLASS TO SUPPLY LIGHT TO SIDE WALLS AND CEILING

and important work places of this establishment is never allowed to fall below 6 foot-candles without immediate correction. By measuring light actually delivered to the work, the foot-candle meter automatically reveals the combined effect of all possible causes of depreciation.

Ignorance of the magnitude of the depreciation which follows the neglect of a lighting system has been responsible for the expenditure of many kilowatt-hours without adequate return. In other words, light saves accident and waste, but light itself, too often, is wasted.

Eliminating Manufacturing Wastes With Machinery

A Recognition of the Importance of Engineering Research and the Extensive Use of Automatic Machinery as a Means of Eliminating Wastes in Labor, Time and Materials—"Watchful Waiting" Policy Must Be Changed to An Offensive One

BY J. E. HIRES

President, Automatic Machinery & Equipment Co.

A STUDY of the development of the use of automatic machinery in manufacturing plants reveals a tremendous revolution in methods and processes in the last century that can be outstripped only by the still further improvement which inevitably must come in the next. From the invention of the cotton gin, to which all of our schoolday American histories point as the beginning of modern industrial methods, to the present-day slogan of many of our food manufacturers—"Not touched by human hands"—there lies in every industry a trail of obsolete machinery and equipment that has furnished many a meal for the scavenger of our manufacturing plants—the junk dealer. In some instances, so quickly have improved machines been produced and so ruthless has been the law of price based on competitive cost that new machines have superseded equipment almost new, but obsolete.

ATTITUDE OF THE MANUFACTURER

One reason perhaps for this very condition has been the failure of the manufacturer to grasp the importance of engineering research toward the improvement of his methods. Too often he has waited for an outsider to build a machine for his business and then been forced to adopt it, after it had already been sold to his competitor, in order to enable him to stay in the business. From an improvement standpoint he has adopted the "watchful waiting" policy, with the result that better machinery has been forced on him as a defensive measure, rather than being developed and patented by him for the benefit of his own business.

This, perhaps, is too severe an arraignment of the managerial ability of our country to pass over without some comment on the other side. It is true that the average manufacturer has found his hands so full in producing his own goods that he has had neither the time nor the capital to spend in building machinery for the production of those goods. It is also true in times such as the "cost-plus war period" just passed that the manufacturer has been more concerned with immediate results than with the building of machinery that will save something six months hence. But in times of depression, such as the present, every avenue of cutting costs must be followed out, and incidentally in nine times out of ten the machinery which is designed and built for the purpose of cutting costs has the added advantage of greatly increasing the capacity for production during the busier days ahead.

LACK OF DESIGNING AND ENGINEERING STAFF

Another big handicap in the manufacturer's path has been the lack of the expert designing and engineering staff which is required to build the needed machinery. He may have and often does have mechanics of ordinary

ability, with good ideas as to how certain processes could be done to better advantage, but they do not have the broad experience in the designing and building of automatic equipment which will bring those ideas into actualities. Furthermore, he cannot find in the average machine shop, that does a general repair and "build-to-specifications" business, the caliber of men who can solve his problems.

CO-OPERATION IN DEVELOPING MACHINERY

The designing and building of automatic machinery is in a way a business in itself, and yet it is a business which must be closely linked up with that of the manufacturer whom it serves. This must be the case for two reasons:

First, the manufacturer must be assured that he will receive the benefit in the way of "patent rights" of any machinery built for him, because after all he or his men will contribute many of the ideas embodied in the final machine. He will give, in other words, the intimate knowledge of the requirements of the business and the idea of what is to be accomplished, while the designer and builder of the machinery, acting in the capacity of consulting engineer, brings to the problem the technical knowledge and skill required to solve it and the broad experience in the construction of similar equipment in many other lines. There is undoubtedly a timidity among some manufacturers toward allowing anyone from an outside company to become acquainted closely with the manufacturing processes in their plants. There is, perhaps, a feeling that their methods are to some extent secret and a fear that ideas gained by an outsider may be carried to competitors in the same line. However, this is not the case in dealing with a reputable company, which is making a specialty of just this kind of business and whose whole business naturally rests upon its careful guarding of its client's interests.

Second, it is only in this manner that the average manufacturer can reasonably approach such a problem. He cannot afford to hire the men or purchase the equipment to design and build his own machinery. The volume of his work would not justify the expense, for men who can do this work cannot be hired at ordinary mechanics wages and some of the equipment required will not be found in the ordinary machine shop. And yet it must not be thought that there is anything mysterious in the perfecting of labor-saving machinery. There is nothing in the business of equipment designing and construction akin to the popular conception of the inventor, producing through divine inspiration or black magic a completely new world wonder. On the contrary, the rules of the business are as simple, the methods as direct, and the results as sure as that of any

other business. Whatever is accomplished is based on something already accomplished. Very often the most valuable work of a consulting engineer in this capacity is simply improvements on present machines, and furthermore many of apparently the most wonderful new machines are based on other machines that have failed. It is simply a question of remedying a defect here or adding an improvement there, which turns failure into success and changes a junk heap into a machine "that almost seems intelligent."

SAVING IN LABOR, CAPITAL AND OVERHEAD

There are certain underlying principles which govern the use of machinery that apply to any manufacturing plant, whether it is making thumb tacks or caramels. These are certain points for which the consulting engineer looks when he enters a plant. The most common idea of automatic machinery is that it is a labor-saver, and it is possible that the greatest saving lies in that direction, although in many cases an even larger saving may be made in materials. For instance, a sirup-filling machine was constructed primarily with the idea of replacing six girls filling by hand with one man operating the machine. The saving made in labor was perhaps \$15 per day per machine. But the greatest saving of the machine was in the elimination of waste due to overfilling and underfilling by the hand method. Shortfills were eliminated and instead of cans going out with one-half ounce too much sirup in them, the net weight could be accurately adjusted by the filling machine to within three one-hundredths of an ounce. Figuring one machine turning out 60,000 cans per day, this meant a saving of 30,000 oz. of sirup, or 1,875 lb., valued in this instance at 10c. per lb., or \$187.50 per day saving. Very often, too, there is a considerable saving in capital as well as operating expenses.

The substitution of mechanical for hand labor invariably means greater production in less floor space. It may mean the dropping of plans for additional buildings which were considered necessary in order to increase production, for in any case where hand labor is used increased production is obtained only by more help, and more help means more room, more boilers, more rest rooms, more office force to handle the larger payrolls, or, in general, more overhead. Another tremendous source of saving is in the elimination of carrying skilled employees over periods of depression in business, simply because they have become so necessary that they must be retained until business picks up. In many industries hand labor is used in processes where it requires months or even years of apprenticeship before an employee becomes efficient. If these employees are discharged in a time of depression the loss to the business in starting up again is often greater than the loss of paying the employees during the idle period.

CONTINUOUS MANUFACTURING OPERATIONS

One of the most common sources of inefficient operation in the manufacturing plant is the lack of continuity in the process. The product starts in one department and has something done to it. It is put down, picked up and trucked to the next department, where something else happens to it, and so on through all the departments of the plant. It may spend days, weeks or months in its journey through the plant, sidetracked at some junction point, just as our freight cars were sidetracked when a troop train went through, and each time it is sidetracked it is put down and picked up again.

Many machines which are not continuous in their operation can be found in plants where the speed of production is determined altogether by the operator who sets the machine in motion and stops it at each operation, and very often with some comparatively slight adjustment those machines can be made to operate continuously and be fed automatically, so that their production is predetermined and not dependent on the personal feeling of the operator. The ideal operation of the plant is a continuous one, from the receipt of the raw material to the loading of the finished product into the freight car, without stopping at any stations en route, where the track might be blocked by an accumulation of stock from the shipment ahead that for one reason or another did not get out on time. This means, of course, the careful co-ordination of the work of different departments. It means the reducing to a common denominator—or, perhaps better, the increasing to a common denominator—of the speed of the process in each department and the installation of carefully planned conveying equipment, which will keep the product moving continuously from process to process at the right time throughout the plant.

USE OF AUTOMATIC EQUIPMENT

Generally speaking, there are certain processes in almost every plant which can be handled automatically, and the perfecting of the equipment to handle them is usually confined to modifying existent plans, so as to meet the special requirements of the individual product. For instance, the filling of liquids into cans or bottles can be accomplished continuously on the rotary principle. The size of container to be filled, the density and viscosity of the product to be filled, all will have a decided bearing on the details of the machine. It is true that if the liquid to be filled is a food product, some special precautions from a sanitary standpoint will have to be taken in the construction of the machine that would not apply if the liquid to be filled were paint or oil, but, again, that is a detail which will not alter the general principle. Similarly the labeling, wrapping and packing of goods, and the conveying of goods in process and finished product can all be accomplished automatically regardless of whether the product is olive oil or soap, camera films or patent medicines, with due allowance being made for the difference in size, shape and weight of the particular packages to be handled.

INTERESTING INDUSTRIAL APPLICATIONS

It is interesting to note some of the particular applications in modern industry. There is the nailing machine for example, which at one stroke makes a completed box as fast as a man can drive a single nail. There is the automatic ticket printing machine, which has taken the printing of theater tickets out of the hands of the local job printer, because he could not compete at twice the price with the automatic machine. In this instance an immense business has been built up based on the patent rights of one machine, that proved such a labor-saver that no other printing establishment was able to compete in its particular field.

There are sealing machines for canning factories that seal a hundred cans per minute and eliminate the labor of fifty operators soldering by hand. Forty per cent of the cost of manufacturing calendars today is in the hand labor required to collate the sheets after they are printed. A machine is now in process of development which will collate these sheets and pad them at

the rate of five hundred per minute. Moreover, the application of such machinery is not confined entirely to hand labor. Frequently it is possible to replace clerical labor by machines, such as coin counters and automatic weighing and measuring machines. There is a machine in the hide and leather industry which automatically measures the surface of a hide, of however irregular proportions it may be. So one might continue endlessly pointing out the saving of time and materials, the increase in productive capacity and the elimination of the labor problem in industry after industry that has been accomplished by the introduction of automatic machinery.

RECOGNITION OF ENGINEERING RESEARCH

The function of this article, however, is to point out the possibilities of improvement through the more extensive use of machinery and to define a reasonable policy which the average manufacturer might profitably follow in order, first, to protect himself against the possible loss of his business through his competitor producing more efficiently and underselling him, and second, to insure to himself the benefits to be derived from the patent rights of new inventions which are constantly being evolved in every line of business. To accomplish this purpose the "watchful waiting" policy must be changed for an offensive one, which starts with a budget for research engineering work and the recognition of the fact that money spent for experimental work in developing new methods and processes is a legitimate and in fact a very necessary part of modern economical production.

PAINSTAKING EFFORT AND EXPERIMENT APPRAISED BY ULTIMATE RESULTS

After the appropriation is set aside for this work, the next point to be realized is that the first machine built to do a given piece of work is going to cost probably three times as much as it ought to cost and three times as much as it will cost to produce identically the same machine after it has been perfected and all the plans and patterns are completed. In other words, the building of the first machine is experimental. Failures in different points will occur and must be overcome. Unexpected obstacles arise, so that the first machine will seem to cost an enormous sum compared with any other machine in the plant or even with identically the same machines which follow it. The excessive cost of that machine, however, must be considered as spread over the other machines that follow it and the money to pay that cost is to be repaid by the savings made by every one of those machines put into use. Automatic machinery cannot be produced out of thin air, or purchased to fill a given need at so much a ton. It requires painstaking experiment and effort and must be appraised in the final analysis, not by what it costs for the first machine, but by what it saves and by the advantage the patent rights give the manufacturer in enabling him to undersell his competitor.

If every manufacturer would take the attitude that the improvement of his methods of manufacture was as much a part of his business as the actual production of his goods and set aside an appropriation for this research engineering work, it is safe to say that in the long run no appropriation he makes will yield any better, surer returns.

Philadelphia, Pa.

Some Causes of Low Production

In the summary of the report of the Committee on Elimination of Waste in Industry (July, 1921), some of the causes of low production are grouped under: Faulty material control, faulty design control, faulty production control, lack of cost control, lack of research, faulty labor control and ineffective workmanship.

The average manufacturer has no calendar of operations except the dates of starting and finishing a job. He largely regulates deliveries of materials by visits to the job, or through statements received from the job superintendent. Haphazard methods of planning result in delays for want of material, or in burdening the job by an oversupply of material. Another waste resulting from inadequate control comes from the speculative purchasing of raw materials. Fortunes are made or lost in this practice.

The defective control of design results in a major waste, since it prevents standardization of product.

The lack of adequate methods of production control is evident in every industry. It is one of the outstanding weaknesses.

It is found that at least ten hours per week per man is thrown away on energy-wasting and time-wasting work resulting from lack of shop methods, while an additional two or three hours per man per week are wasted in unnecessary work. The lack of production control is not a question of large versus small plants. Some of the large plants as well as some small ones show a large waste factor.

The majority of the industrial plants studied lack a knowledge of costs and have no cost control. Therefore there is no adequate method of judging fairly and accurately when improvements are needed and when waste is occurring. This prevents prompt correction of defects.

While certain industries are ahead of the rest in plant research, the need for more intensive research activity is apparent in every industry.

The cancellation of orders is a condition peculiar to certain industries. Purchasers buying on long-time contracts return unsold goods at the end of the season, and claim and receive credit.

LABOR TURNOVER AND INEFFICIENT WORKMANSHIP

A high labor turnover is a rough index of one of the common wastes resulting from inadequate labor management. This is an important factor of labor waste because of its magnitude and because of the expense involved in training new workers to take the place of those who leave. Employment managers are rarely employed even upon the largest jobs, and "hiring and firing" is at the will of the foreman or superintendent. Another fault in labor control is improper or inadequate rate setting. If the rate is set too high, it means unequal payments to the workers or else cutting rates later on. This policy is responsible for much of the friction in industry.

Another loss resulting in low production arises from inefficient workmanship. For much of this management is responsible through failure to provide opportunities for education or special training. Management cannot, however, do more than provide these facilities, and experience has shown that it is difficult to interest workmen in training courses which are designed to increase effectiveness. Further, much ineffective workmanship arises from lack of interest in work or lack of pride in good workmanship.

Elimination of Waste in Industrial Power Plants

Shall an Industry Own Its Power Plant or Buy Its Power?—The Determining Factor
Is the Relation of Heating and Process Steam to Power Demand—
The What and Why of Fuel Economy

By DAVID MOFFAT MYERS
Consulting Engineer

IT IS an interesting fact, and one little realized, that the factory power plant possesses an enormous advantage in the production of economical power, an advantage entirely lacking in the modern central station of our "superpower" ideas. The fact may be very simply explained. The central or so-called "superpower" station has a single object to fulfill—i.e. to supply consumers with power and with power alone—whereas the natural and unavoidable product of every steam-power plant is not only power but heat as well. And furthermore, this product divides itself (again unavoidably) into about 20 parts of power and 80 parts of heat. These 80 parts of heat are absorbed by the cooling water of the condenser and wasted. The condenser's one object is to assist in converting the largest possible proportion of the heat of the steam into power and is necessary for this purpose. When a condenser is not used, 86 to 95 per cent of the heat is available in the exhaust for heating and about 4 to 12 per cent converted into mechanical energy.

This represents the best that can be done in actual practice in our effort for efficiency when power alone is the object sought. The waste of steam, heat and fuel to the condenser is in the average case four times as great as the useful energy produced. Natural laws have bound us to this narrow limitation, which may be only slightly improved as we learn how to construct steam power apparatus for still higher steam pressures and greater temperature ranges.

The central plant has no market for this heat, to produce which it has been compelled to consume four-fifths of its coal.

USE OF EXHAUST HEAT FOR HEATING PURPOSES

The usual industrial plant, on the other hand, has frequently a very large demand for heat as well as power. In many cases and in numerous kinds of manufacture all or the major part of this exhaust heat can be utilized for processes and for the heating of buildings. In the majority of industrial plants heat is needed for the plant during the cold months of the year. In all such industries all or a portion of the otherwise wasted heat which is a pure byproduct of their power generation can be effectively utilized to take the place of its equivalent of direct steam from the boilers. Thus, for example, in an industry where there exists a large demand for heating and process steam the economy of

the situation would be represented approximately by the following comparison:

Case 1. Combination power and byproduct heating. Five to 10 per cent of the heat of the steam converted into electrical energy to supply the power demands; 90 per cent or more for heating and process work; no steam wasted.

Case 2. Power and heat from separate sources, the former from a superpower plant, the latter from a boiler plant in the industrial establishment. The boiler plant will have to produce 90 per cent as much heat (steam) as in case 1, and at the same time it will be necessary to buy power which has been made with an 80 per cent waste of steam and is consequently proportionately expensive, since the consumer must pay for the 80 per cent waste of steam as well as for the power.

Each industrial plant has its own particular requirement for so much heat and so much power, but the more heat it requires the more cheaply can it make its own power as a byproduct of its heating and process steam. There are many plants which require little or no heat. Here power alone obtained at the lowest cost is required. Whether such an industry should own its plant or buy its power is purely a question of the engineering economies of the situation.

Modern central stations can produce power more economically than the small industrial power plant when power alone is wanted. The losses over long and costly transmission lines both electrical and financial must be considered, however, in the case of central station power.

THE FIELD FOR SUPERPOWER

Superpower as now conceived has its legitimate range of service and will find its appropriate and economical field of consumption in those industries, principally the medium and smaller sized plants, where the heating requirements are relatively small, and in some cases where capital might earn more when invested in factory extension for increase of production than in the building of a power plant. Then there are also many plants where the necessary heating may be largely accomplished by surplus heat from process furnaces, kilns, etc. In such the outside power may often be supplied with the best possible results.

From the standpoint of steam and fuel conservation, however, the operation of the superpower station as now planned is exactly comparable to that of an industry which throws away 80 per cent of its partly finished product. The directors of such an undertaking would not rest until some valuable market were found for turning this huge loss into profit. By the same logic a new conception is needed of what could more truly be termed superpower. Such a conception at once in-

¹"Superpower" as produced refers to a rather large extension and improvement of our existing system of electrically connected steam- and water-power plants along the north Atlantic seaboard. It is estimated that possibly 15 per cent may be water power. Congress some time ago appropriated funds for preparation of a report designed to show the cost of executing this plan and the economies which might result. The plan aims to supply efficiently made energy for general railroad and industrial consumption with the hope of eliminating many small power plants apparently less efficient and to reduce the coal carried by the railroads by transmitting the equivalent energy in the form of electric current.

volves the necessity of a market for the byproduct heat of the power plant, and this immediately presents a picture of what has already been accomplished together with a vision of further possibilities and economies. In many industries exhaust steam has been utilized to the fullest extent, with the consequently specific economy of byproduct utilization. There are many well-tried specific means and equipment, prime movers and heating systems for effective execution of such combination of heat and power. And these of course require engineering judgment and experience in their correct selection and arrangement. The point is that such truly efficient plants have for long been a proved and accomplished fact.

IMPROVE CENTRAL POWER STATIONS

The next step is to improve our central power stations along the same general lines as far as possible. In large cities the stations now selling power only should revise their policies toward real fuel conservation and plan for the development of combined heat and power systems so as to furnish both commodities to present consumers. Isolated cases have already been reported and in one case the income to the central station from the sale of heat alone paid for the cost of its power production. The block system of central heat and power plants should be further developed. If modern heat and power stations could be built near large industries requiring both heat and power, great economies in steam and fuel would be effected.

ELIMINATION OF WASTE IN RELATION TO POWER

It has been stated previously that superpower talk is in the air, and every factory owner and manager is concerned with its relations to his own power problem. I have therefore introduced my subject by presenting a few fundamental facts which may assist to some extent in a clearer understanding of how this power is produced and how it may or may not economically apply as a source of industrial power in any particular case, each of which must be skillfully diagnosed on its individual merits and in accordance with its local conditions.

While it is quite logical and often appropriate to begin a discussion of power plant economy with the fuel supply, the boiler plant and its generation of steam, then the distribution and various applications of the steam, I have elected a different order of treatment in this case and for this reason: In the industrial power problem both from the standpoint of operation and of design, which includes the question of purchased power, the determining factor is almost always this element of heating and process steam in relation to power demand. I am therefore placing this determining factor first with the object of getting for it the emphasis to which it is properly entitled.

It is an economic blunder of the first magnitude to use direct steam for heating or process work without first deriving from that steam its quota of mechanical or electrical energy, when such application is available. And conversely it is equally poor engineering and bad business to use steam for power generation alone when it is possible to utilize the large percentage of byproduct exhaust heat for manufacturing processes or for heating buildings.

I very often find prevailing among owners and managers the idea that low-pressure steam can be made

much more cheaply than high-pressure steam, and they therefore feel that if they could eliminate their engines and turbines and make low-pressure live steam for heating instead of using exhaust from engines a great saving in fuel would be effected. As a matter of fact, at the same boiler and furnace efficiency exactly the same amount of fuel is required to supply the same quantity of heat whether the steam is at 1-lb. pressure, at 100 lb., or any other pressure. The only gain possible might be 1 to 3 per cent better boiler efficiency due to lower flue temperatures made possible by lower steam and boiler temperature.

It was formerly thought impracticable to use exhaust steam except at very low pressures. Ten- to 30-lb. pressures are now rather common. And as I write I have in mind a large rubber-manufacturing plant where a 10,000-kw. non-condensing turbine is being installed to take steam at 250-lb. pressure and exhaust into vulcanizers at 80- to 100-lb. pressure. The electrical energy so generated will be virtually a byproduct of the direct steam formerly used by the same vulcanizers as far as fuel is concerned, and its total cost per kilowatt-hour will be a very small fraction of the cost at the plant of energy delivered from a modern and efficient power station located directly at the mouth of a coal mine only ninety miles away.

Where all the exhaust steam can be used, a common old-fashioned slide valve engine will produce byproduct power in a factory for a fraction of the fuel required for the same power made by a modern steam plant operated condensing.

EXTRACTION TYPE OF STEAM TURBINE USEFUL

Where all of the exhaust steam cannot be used all of the time, the extraction type of steam turbine may often furnish the solution. This turbine, which operates condensing, is designed so that exhaust steam can be drawn from between the high- and low-pressure stages after doing work and producing electrical energy through the higher range of expansion. When less exhaust or extraction steam is needed, the surplus automatically passes on through the low-pressure stages of the turbine to develop more electrical energy and permits the throttle to cut down the use of the equivalent live steam from the boilers. In this way a steam balance is maintained for all combinations of heat and energy demand. There are several other methods of producing this desirable balance of heat and power without waste of exhaust steam, which can be applied in accordance with conditions and requirements.

There is also the mixed pressure type of turbo-generator. This operates condensing on low-pressure steam with provision for automatically receiving direct steam from the boilers in case the imposed load and available exhaust so require. Thus in case there exists in a plant a surplus of exhaust steam for which there is no heating demand this exhaust steam can be made to produce electrical energy.

The distribution and application of the heat of exhaust steam have become very efficient with the development of modern methods and equipment. Among these should be mentioned the vacuum return line system of low-pressure heating; the forced hot water system of circulation; automatic thermostatic control and the improved methods of air conditioning, ventilation and drying.

Having now touched with some emphasis upon the "determining factor" (the relation of heat to power)

in the economy of industrial power supply, the matter of next importance is the boiler plant.

Economy is the product of two elements—design and operation. The final efficiency is equal to the efficiency of the equipment multiplied by the efficiency of the management; or the efficiency of the machine times the efficiency of the brain; the machine multiplied by the man behind it. This means that you can, without redesigning your old plant, very considerably improve its efficiency and economy, unless your plant happens to be one out of a thousand, which a thousand to one it is not. This is the principle upon which the Fuel Engineering Section of the U. S. Fuel Administration was based during the war, and it resulted in saving 25,000,000 tons of coal annually by improvement of operation without change of equipment. This saving would have been doubled if there had been time to perfect the organization and fully extend the work.

USE OF "WHAT INSTRUMENTS"

The first step is to make sure you are getting the best possible results from the equipment you already have. You should have the means of knowing every day the results you are getting. The essential figure you need to know is equivalent evaporation per pound of coal. The obtaining of this information involves the continuous measurement of weight of feed water or steam, weight of coal and feed water temperature and steam pressure. These together with occasional B.t.u. determinations of the coal used, will enable you to know the efficiency of your plant and how it compares with standard efficiencies for your kind of coal and equipment. These instruments tell what results you are getting, and may be termed the "what instruments."

USE OF "WHY INSTRUMENTS"

Then when you find your results are too low, you will want to know why, so that you will be enabled to correct the preventable waste discovered. The determination of the causes of the waste is made by another class of instruments, which should be known as the "why instruments." In this class belong flue gas analysis apparatus and flue pyrometers which will check the one greatest loss in most boiler plants—the "dry gas chimney loss"—and the pyrometer will also indicate losses due to short-circuiting of gases and leaky baffles. Draft gages are also "why instruments." It will pay good dividends to apply a plastic airtight coating to the outside surface of all brick set boilers to stop air leakage, and be sure that all clean-cut doors and their frames receive due attention as well as header and other connections where air leaks are likely to occur. I have found in a "good" plant as much air leaking through the settings as was passing through the grates.

HOW MEASURING INSTRUMENTS PAY

Good judgment is required in selection of boiler plant instruments so that reliable records may be obtained. The records must be reduced to utmost simplicity without omitting essentials. The instruments must be chosen with regard to size of plant and human equipment, so that they will not cause an undue burden on the operating staff.

In one small plant where I recommended a very simple form of coal and water records alone, the evaporation was increased from 6 to 9 lb. per pound of coal and the equipment was paid for in about two months by the saving in fuel.

In another plant where the coal and water were already under measurement, continuous CO₂ recorders ("why instruments") were installed and resulted in additional savings which paid for the investment in three months. These instruments were used in conjunction with a simple bonus system for the firemen and shared by the engineer whose duty it was to keep the recorders in perfect order.

In the average factory plant very large savings can be made simply by operating the boiler plant on a production basis on the same principles which are always applied to the other departments of the business. The investment possibilities of so doing are very great; so great that it can be laid down as a definite, inflexible rule that every boiler plant should be placed under a suitable system of continuous records and observation. Ten per cent of the fuel consumption is a very conservative estimate of the resulting economy which follows such a plan when intelligently applied. This statement is based on experience in many plants of great variety. A simple change in the method of handling the fires often results in saving thousands of dollars a year in fuel. The need for such a change would not be discovered unless the "what measurements" and the "why instruments" showed the corrections to be applied. A quarter of your coal bill may be wasted or saved merely by the method of operating employed, without regard to the design of your plant.

RULES FOR FUEL ECONOMY OPERATION

A few simple rules for fuel economy operation follow:

1. Maintain your equipment in first-class condition.
2. Keep the boilers clean, inside and out. This means free from scale and sediment inside and free from soot and dust outside the heating surface.
3. Keep soot from obstructing draft passages in breeching and chimney.
4. Employ instruments to know what results you are getting and why. Multiply these records and observations by your brains. In other words, make use of them.
5. Buy some brains and training, as well as brawn for your fire room. They cost more and they are worth more. They always pay good dividends. If I were allowed but a single recommendation, that one would be my choice. If you follow it, you will rejoice in good combustion with the savings consequent thereto, and many other economical blessings.
6. All surfaces wasting heat by radiation, such as steam piping, steam drums, feed-water heaters and other equipment, should be kept properly covered with high-grade insulating material. In one small plant \$3,000 per year could be saved in this way. Insulation always pays good dividends.
7. See that the feed-water is heated by exhaust steam. There is 1 per cent economy in every 10 to 11 degrees rise in the temperature of the feed-water when so heated.
8. Steam-consuming apparatus must, of course, be kept in prime order, but of course it is not always done. Thousands of tons of fuel are wasted through leaky and badly set engine and pump valves, to say nothing of leaky pistons and rings; then there are also leaks in steam piping and waste through badly operating steam traps and high-pressure drips. These things are so simple that one hesitates to record them, but the waste of fuel through these simple and foolish channels is so great that a good operating engineer can frequently make a reputation by correcting them. Be sure you have a good operating engineer and don't skimp on his salary. He will earn it many times over.

ACTUAL EXAMPLES OF LARGE DIVIDENDS

I shall leave the rest of this story with him and shall now proceed to a story or two of what is accomplished when good operating and good designing are joined to-

gether as one. Although these stories are from my own experience, they can be duplicated from the note book of many a contemporary.

First there was the case of a steel company where \$50,000 investment in better stokers, automatic coal scales and a little system of records returned \$60,000 per year in fuel savings, or 120 per cent interest on the "securities" purchased.

One of the largest rubber companies in which furnace improvements, new chimneys, a boiler water softener and plant recording instruments with a system produced a saving of \$850,000 a year for an investment of \$683,000, or an interest return of 124 per cent.

In a woolen mill, a small one, where the heating had been done by direct steam from the boilers and the power supply was partly from its own compound condensing engine and partly from purchased current, a saving of \$8,000 per year in the cost of current was made with an investment of \$5,000, or a return of 160 per cent. This was accomplished by placing a non-condensing unit between the boilers and the heating system to supply the latter with exhaust steam in place of direct steam and deriving from this engine-unit by-product power to replace the purchased power.

In a large wire mill a large saving was made by purchasing power at a low rate instead of extending and improving the power plant. The saving was chiefly due to the fact that the owner was able in this case to get a quicker return on capital invested in the expansion of his production facilities than could be obtained by investing in power plant extension.

LARGE DIVIDENDS FROM IMPROVED METHODS

In another plant it was found by the preliminary study and investigation that an economy of \$40,000 could be made in fuel and operating expenses by spending \$148,000 on the remodelling of the existing plant which included provision for doubling the power output and for additional steam capacity. This work included a change in the kind of coal to one giving a greater quantity of heat per dollar delivered, the installation of suitable automatic stokers, labor-reducing coal-handling equipment, overhead feeder bunkers, automatic individual coal scales and feed-water measurement; the installation of an extraction type steam turbine unit to handle the power and heating demand in the most efficient manner, and improvements in electric power and distribution. The turbine was designed not only as an extraction machine but also to receive and convert into electrical energy any surplus exhaust steam available in the summer months.

In another plant manufacturing a variety of standard articles an opportunity was found to produce an operating saving of \$260,000 annually by the expenditure of \$250,000. A large factor of this economy was the fullest application of exhaust steam to building and process heating, thus reducing the combined cost of heat and power to a minimum.

It must of course be realized that it is impossible to treat with any pretense of thoroughness so great a subject as the Elimination of Waste in Industrial Power Plants in the very limited space here afforded. It is hoped, however, that the few suggestions I have attempted to indicate will assist to some extent in stimulating the kind of productive thought that precedes action.

New York, N. Y.

Estimated Savings With Superpower Central Stations

At the meeting of the Worcester Section of the American Institute of Electrical Engineers, Feb. 2, 1921, Henry Flood, engineer-secretary of the Superpower Survey, in speaking about What Superpower Means to the North Atlantic Seaboard, quoted a few figures which may best cover the potentiality of superpower central stations.

Nearly 40 per cent of the total value of manufactured products in the United States come from the north Atlantic seaboard region, and 35 per cent of the country's power is generated there.

This industrial supremacy can easily be visualized from the fact that one out of every eight persons living therein is an industrial worker, while for the remainder of the country there is only one out of every twenty-five persons so employed. New England is even more intensely developed from the industrial viewpoint, as one out of every 6.4 persons is a wage earner in its factories.

As great as are the power requirements of the region today, they are small compared with those of tomorrow.

The unassociated total power requirements have increased from about 15,000,000,000 kw.-hr. in 1910 to about 27,000,000,000 kw.-hr. in 1920, with a corresponding increase in machine capacity from 8,600,000 kw. to approximately 14,800,000 kw.

ESTIMATED GROWTH OF ENERGY REQUIREMENTS

It is estimated that the power growth for the next decade will increase the total energy requirement to about 50,000,000,000 kw.-hr., and assuming the superpower to be in operation, about 18,700,000 kw. of machine capacity will be required to satisfy this load increase.

Electric public utilities furnished in 1920 about 12,000,000,000 kw.-hr. with a machine capacity of 4,000,000 kw., and it is predicted that by superpower operation the power to be furnished from central supply sources will grow to about 36,000,000,000 kw.-hr. by 1930 and will require a machine capacity in the neighborhood of 9,000,000 kw.

These estimates, which are conservative, call for 5,000,000 kw. additional power-plant capacity in the central supply systems during the next ten years, an increase of 125 per cent over the power plant capacity now in existence.

In the manufacturing industry the estimated power requirement of 1920 has been placed at 12,400,000,000 kw.-hr., and it is estimated that the central-station systems supplied about 2,750,000,000 kw.-hr. of this total requirement. By 1930 it is conservatively estimated that the total power load of manufacturing industry will increase to about 19,000,000,000 kw.-hr. and that superpower can economically furnish at least 10,000,000,000 kw.-hr., or slightly over 50 per cent of the total.

Had superpower been in operation in 1920 a saving of about 30,000,000 tons of coal having a value of about \$162,000,000 could have been effected through its economies over the present performance of central stations, steam locomotives and isolated manufacturing plants, and by 1930 the superpower system should effect a saving of 53,000,000 tons per annum, with a value of \$286,200,000 when compared with present practice.

The Patent Situation

Inadequate Salaries and Insufficient Personnel Are the Causes of Waste in the Patent Office for Which Industry Must Pay in Costly Delays and Burdensome Litigation—Analysis of Legislation Designed to Remedy the Situation

By EDWIN J. PRINDLE

Chairman Patent Committee of the American Chemical Society

OUR patent system is of the first importance to the industrial prosperity of our country; but, until comparatively recently, it has worked so steadily and unobtrusively that the American public has come to be almost as unconscious of it as of the force of gravitation. The interruption of the patent system would be almost as disastrous to our successful competition with the rest of the world in manufacturing, agriculture and inventing as would be that of the law of gravitation to our physical lives.

The public has been apt unconsciously to think that inventions would be produced at the same rate whether or not there were a patent system and that our patent law simply imposed an unnecessary taxation, not realizing that if it were not for the inducements held out by the patent law the articles whose prices are objected to would not be produced at all.

SALARIES ARE UNATTRACTIVE TO QUALIFIED EXAMINERS

This attitude on the part of the public has so far affected Congress that, although the Patent Office is the only self-supporting bureau under the Government, its examiners are not even paid as well as scientific and legal employees in other bureaus which are not self-supporting. For instance, the salaries of the primary examiners of the Patent Office were fixed in 1848 at \$2,500 per annum, which was one-half of the salary of the Chief Justice of the United States and was substantially equal to the salaries then paid United States District Judges and members of the House of Representatives.

In the seventy years since that date the examiners' salaries have been raised but 10 per cent, while the other salaries mentioned have been raised 300 per cent and more.

As the practice of patent law outside of the Patent Office is a profitable profession, the Patent Office became very largely a training school for patent lawyers, who left it as soon as they felt properly equipped for outside work.

There has been a class of examiners who would prefer life in the Patent Office, with its dignity and security, if the salaries were anywhere near adequate, even though the salaries and profits in the practice of patent law outside of the Patent Office would be much larger. The gradual rise in the cost of living being greatly increased by the war, it became not only impossible for many examiners to exist upon the salaries paid in the Patent Office, so that they have been resigning at the rate of 25 per cent of the total force per annum, but it also made the Patent Office positions so unattractive that it has been impossible to induce sufficient men who have the proper educational qualifications to take the examinations to fill the positions. It has therefore been necessary to appoint unqualified persons as examiners,

and there is now a considerable percentage of unqualified persons filling those positions. More than 10 per cent of those now performing the duties of examiners in the Patent Office have not been able to pass the qualifying examination.

EXAMINER'S DUTIES ARE OF UNUSUAL IMPORTANCE

The war has taught the nations involved in it to be efficient as they have never been before, and a number of them have been improving and strengthening their patent systems. Our patent system has shown by its wonderfully successful operation that in its fundamental principles it is the best patent system in the world, but it did not begin to be so supremely successful until we adopted the principle of granting patents not only exclusively to those who were the original and first inventors of the inventions in question, but also only for those inventions which were not known to the American public nor, broadly speaking, accessible to them through the patents or publications of other countries.

It is chiefly for the determination of these two questions that the Patent Office exists. That determination requires that the examiners shall be thoroughly versed in patent law, and they should also be well versed in law in general. It also requires that the examiners should have a deep historical, theoretical and practical knowledge of the classes of inventions under their jurisdiction. They should be able to comprehend and analyze the fundamental principles underlying an invention. They should also be capable of seeing whether similarities or differences between previously known or rival inventions are matters of substance or only matters of form, and of distinguishing between differences which, although comparatively slight, are yet of substantial commercial and inventive importance and those differences which, on paper, may seem to be considerable, but really are unworthy of a patent.

They must either know or be capable of finding out and understanding the law which is applicable to the particular state of facts before them or, as is occasionally the case, they must make new law by applying the basic principles to a state of facts which has no parallel in the recorded decisions. Examiners often pass upon inventions which are of very large importance to their inventors and of much greater importance to the public, and such large interests should only be intrusted to the best qualified men who can possibly be obtained by any reasonable salaries.

PATENTS SHOULD BE GRANTED WITH REASONABLE PROMPTNESS

The situation of the Patent Office has become desperate. The volume of work has increased very rapidly year by year for a considerable time, and the field of search necessary to be covered to determine the ques-

tion of validity has become broader and broader. However, the number of examiners has been increased only to a proportionately slight extent, the examining corps, as a whole, all the while having been weakened by the changes in it before mentioned. The result is that the Patent Office has become more and more unable to keep the quality of its work up to its former high standard, and it has also fallen farther and farther behind in turning out its work. In many cases unless a patent is granted with reasonable promptness, it might as well never have been granted, so far as the inventor is concerned, for the opportunity of disposing of it or of putting the invention on the market will have passed.

INVALID PATENTS ARE LOSSES TO GOVERNMENT AND INDUSTRY

Moreover, the effort to keep from being submerged by the constantly rising flood of work has made it more difficult for examiners to make their searches thorough enough to determine whether the inventions are novel or not. The result is that patents which are partly or wholly invalid are being granted with increasing frequency. This is a very serious matter. An invalid patent means loss to the inventor and others who invest under it, and it may mean a very burdensome expense in litigation to one accused of infringing it and to the Government through taking up the time of the courts. These avoidable delays and defects in the Patent Office work tend strongly to discourage the production of inventions, and if they are allowed to continue and increase, the Patent Office will practically cease to function. Without considering the loss to individuals, which is serious, the loss to the American public would be incalculable if the Patent Office is permitted to become further impaired.

While it is not generally realized, it is nevertheless a fact that there is no one activity of our Government which is more important than the maintenance of the patent system. It has made us the most inventive of nations and enabled us to maintain the foremost position in manufacture and agriculture. Our unusual inventiveness is due almost wholly to our patent system; for Americans, being Europeans by extraction or immigration, are no more inventive naturally than the people of the nations with which we compete.

LAMPERT PATENT OFFICE BILL

In an effort to remedy this situation, the National Research Council appointed a committee at the request of the Patent Office, which, after investigation, formulated and obtained the introduction into Congress of a bill very moderately increasing the salaries and numbers of examiners and the clerical force of the Patent Office. The salary which the bill proposed for a primary examiner was but \$3,900 per year.

This bill received the support of the American Chemical Society, the Federated American Engineering Societies, the National Association of Manufacturers and many other organizations. In fact, the scientific, engineering and manufacturing societies and interests of the country were practically a unit in favor of the bill.

The bill passed the House of Representatives and would have passed the Senate but for the fact that an unrelated section, known as the Federal Trade Commission section, was introduced into the bill by amendment in the Senate, and opposition to that section pre-

vented the passage of the bill. In the present Congress, the bill has been re-introduced as the Lampert Patent Office bill, H.R. 7077. A favorable report upon it was unanimously voted by the Patent Committee of the House of Representatives, and the bill would apparently pass the House if it could be brought to a vote. The policy of retrenchment is understood to be preventing such action, the Government not realizing that the net effect of the Patent Office bill not only will not increase the expenses of the Government, but, on the contrary, will increase the income of the Government. Not only will the increases in salaries provided by the bill be paid out of the increased fees which the bill provides shall be charged for patents, but restoring the Patent Office to normal and efficient operation will result in the production of wealth in the form of inventions that will provide incomes affording taxes that will substantially increase the income of the Government.

NOLAN TREATY PATENT BILL

The Nolan treaty patent bill was passed in February, 1921, in response to an emergency resulting from the war. Under existing treaty provisions and our law, an inventor is given one year, after filing an application for patent in his own country, within which to file applications in treaty countries, with the same legal effect as to priority over other inventors as if his applications had all been filed simultaneously. In case of a contest with another inventor in one of the countries foreign to the applicant, the inventor is given the same benefit of priority as he would have had if all the applications for the patent had been filed simultaneously.

During the war many inventors in the countries foreign to the United States were unable to take advantage of such treaty provisions, and many American inventors failed to file applications for patents abroad, because they were in war service or because they did not know whether the outcome of the war would make foreign patents worthless and they likewise failed to pay annual taxes on their patents. The European countries extended the time within which applications could be filed or fees paid and our Government passed the Nolan treaty patent bill in order to reciprocate. If such bill had not been passed, the European countries would have invalidated applications for patents and payment of fees which they had accepted from American inventors in the expectation that such a bill would be passed here.

The bill protects American inventors and manufacturers to the extent that it reserves a license under any patents granted or validated by reason of such act to any American citizen who, before the passage of the bill, was *bona fide* in possession of any rights in patents or applications for patents which might conflict with any of the patents applied for by aliens, and the bill also preserves to any citizen of the United States, his agent or successor in business the right to continue any manufacture, use or sale commenced before the passage of such act by such citizens, even though such manufacture, use or sale might infringe a patent granted or validated by the said bill.

STANLEY COMPULSORY WORKING AND LICENSE BILL

The Secretary of War found that a considerable number of war inventions made in this country were being patented by others than their real inventors and the patents assigned to the Krupps in Germany. He therefore caused the Stanley bill to be introduced in Con-

gress to prevent aliens from patenting inventions here and then using those patents to enjoin the manufacture of the inventions in this country. The preventive measure is a condition to be inserted in the grant of all patents to aliens to the effect that any patents issued to persons who are not citizens of the United States shall be worked in this country within two years from the date of issue under penalty of having licenses granted under them by our Government to others who wish to work them in this country.

I believe that the bill is of doubtful efficacy to accomplish its purpose and is extremely unwise when considered in all its reactions. If an invention—and particularly a chemical one—were important enough for the Germans to want to prevent manufacture in this country, it would be worth their while themselves to manufacture here sufficiently to prevent the granting of licenses. This would tend to bring about the German manufacture here which we tried so hard to eradicate during the war, under the name of “peaceful penetration.” If the invention were not one of sufficient value to make it worth while for the Germans to manufacture here, it would probably be one concerning which Americans would be indifferent as to whether it was manufactured or not. If the bill really hurt the Germans, then it would tend to induce them to keep secret all inventions which could be kept secret, and not to patent them. This course would deprive the American public of the knowledge of the inventions which they would derive from patents therefor and which they would be free to put in practice when the patents had expired.

OBJECTIONS TO THE STANLEY BILL

The Stanley bill would be in contravention to the Geneva International Convention, to which the United States is a party, as this convention provides that each country shall grant to the nationals of the other countries which are parties to it the same rights and privileges as they do to their own.

The enactment of the Stanley bill would undoubtedly result in the enactment of similar provisions in most or all of those countries which do not now require that American-owned patents shall be worked, so that Americans would be required to work most of their foreign patents. As there are many more American-owned foreign patents than foreign-owned American patents, the net result would be a disadvantage to our country.

In and out of Congress there is some sentiment in favor of applying a compulsory working requirement under penalty of having licenses granted to all United States patents without distinction as to whether they are granted to American or other inventors. If the Stanley bill were enacted in its present form, there is danger that it would be used as an entering wedge for such a general working requirement, and it is even possible that the present bill would be expanded for that purpose. I believe that such an amendment to our patent laws would be a catastrophe.

The test of the advisability of enacting the Stanley bill or any bill should be whether it will tend to increase or discourage the production of inventions, and if the advantage is not clearly in favor of such a bill it should not be enacted. It is dangerous to try experiments, for the common inventive faculty having been slowly developed through generations, it would take many years to restore it after it had become atrophied through disuse.

The following are some of the objections to a compulsory working requirement:

Many an invention which well fulfills its particular object is “ahead of its time” and is of no commercial value until the art and the commercial conditions with which it must co-act have grown up to it. This frequently does not take place until the later years of the patent, and of course may require many years longer than the monopoly of the patent. The cost of working an invention is almost always considerable—frequently very large—and if it were required that each patent should be worked within two years after issue, the working of such an invention would often be a total loss. Frequently the patentee would not be able to work it and would permit the patent to lose its salability, for a patent cannot usually be sold unless the complete monopoly, without any outstanding licenses, can be transferred. If, during the later years of the monopoly, it should appear that the patent would have been valuable if it had been worked, the inventor would be embittered by his needless loss, and many of those who would know of his experience would be deterred from inventing.

Any development to produce an invention goes through a course of evolution. Processes of manufacture and apparatus or machinery for that purpose frequently have to be invented. Auxiliary inventions often have to be made. Thus there is usually a group of patents that are necessary to protect the development and to prevent others from discovering and patenting some of the inventions in the group. Such a development frequently takes a number of years to reach a conclusion, and until that time it cannot be told whether there will be anything of sufficient value to be worth while putting on the market. Still, under the Stanley bill, it would be necessary to work each of these patents, which is in effect a fragment, within two years after its issuance, under penalty of having licenses granted to some competitor.

DISCRIMINATES AGAINST THE POOR INVENTOR

The Stanley bill discriminates between the rich and the poor inventor. The poor inventor would usually not be able to work his patent. Our patent system has been the door of opportunity, through which many men in the United States have risen from poverty to wealth. In so far as applying for and obtaining patents, in which there were no interference contests, and retaining the monopoly of those patents unimpaired, our patent system has heretofore treated all men alike. It should continue to do so.

The cost of working patents would greatly decrease their salability, for many corporations even would not buy a patent with such an expenditure attached as a certainty, and the purchaser would always pay much less for a patent carrying such a condition.

Many inventions which are patented under our system are of relatively small ingenuity, and often of no commercial value to their inventors, and yet, taken together in a single art, they occasionally lead the way to a point of view from which someone sees an opportunity to make a really important invention. These small inventions would not be made or patented if there were a general compulsory working requirement in effect in this country.

The compulsory working requirement in this and in other countries has not proved of substantial benefit.

New York City.

The Elimination of Waste in Marketing

Marketing From the Point of View of the Manufacturer Can Be Made More Profitable by the Application of Better Methods of Distribution and by the Establishment of Improved Selling Policies

BY WILLIAM R. BASSET

Miller, Franklin, Basset & Co., New York

WE ARE frequently told of commodities which double and treble in price between the producer and the consumer, the blame being laid on faulty methods of distribution. Careful thought is not commonly an activity of the publicity-seeking fault-finder nor of his eager readers, therefore it does not occur to most that the profits of a long string of middlemen and handlers cannot be tacked onto the ultimate price unless consumers want the product badly enough to pay the price. The buyer makes the price ultimately—not the seller. In normal times—which comprise about ninety years out of each century—the buyer will not pay the charges of middlemen unless those charges represent a service which the customer values more highly than the money it costs him. Ask any of the financially dead or dying middlemen who sprang up in nearly all trades between 1915 and 1920 if this is not so.

As a consumer, I of course acclaim any reform which reduces prices, but in my professional capacity I am more interested in seeing the profits of producers increase. And that is not incompatible with constantly reduced prices to buyers.

I shall therefore in this article discuss faulty marketing from the point of view of the manufacturer, to whom such wastes represent unnecessary deductions from his profits.

Right off, it occurs to us that manufacturers may be classified as those who do not do their own marketing and those who have some degree of control over their marketing.

INDUSTRIES IN WHICH MIDDLEMEN FLOURISH

The manufacturers who do not do their own marketing are generally those whose product is more or less staple, who sell an un-trademarked, unadvertised product in bulk through factors, brokers, wholesalers, speculators, or anyone with the price. It is in industries of this sort that middlemen flourish, for it is they who presumably furnish the knowledge of the consuming markets which the manufacturers lack.

Frankly, I have never been able to understand the mental process of a manufacturer who, while retaining but a narrow margin of profit himself, will trust his marketing—even his very existence—to the mercy of middlemen who have no object in safeguarding his affairs. The usual explanation which such men make is that they are skilled manufacturers but are not salesmen; that they prefer to leave the selling to others more skilled in it; that a selling organization is a nuisance and an expense; and that by dealing with a few large distributors they avoid the effort and risk of handling multitudinous small accounts; that, being relieved of all these details, they can give their entire attention to producing, at which they are skilled, and, by improved processes, make more money than they would gain by improved marketing. The trouble is that, failing an

individuality and reputation both for their business and for their product, they must compete practically on price alone, which keeps their margin of profit down, no matter how much they improve their methods. Their attitude suggests that they are, in fact, too lazy to study and master marketing technique.

However, every year a few of these old-established concerns reform and take over their marketing, and I believe that within a few years most of them will have joined the procession or have dropped out.

Ignorance of selling on the part of the members of the firm is not a valid excuse, for they can, if they wish, have their marketing problems solved by any one of dozens of advertising agencies which are highly skilled and which will outline every step in marketing in accordance with the peculiar needs of their client.

Manufacturers who exercise some degree of control over their marketing range all the way from those who sell directly to the consumer to those who sell through wholesalers. But they have in common the realization that to be permanently successful they must have a business personality. They know more or less accurately who buys their goods and why, and they know that control of their marketing, while it entails effort and expense, returns more than enough profit to offset it. But the wastes in marketing of concerns like this cannot be solved with a gesture, for they are complex and hidden.

CONTROL OF MARKETING BY COST ACCOUNTING

The control of marketing is seldom based on an accurate knowledge of those facts which would unerringly point out where profits lie. I concur in the statement made by a well-informed commercial banker that "best sellers" in a line are properly objects of suspicion. Too often they are easy to sell, not because of their merit, but because they are unwittingly sold at a loss.

I know of a concern which manufactured fourteen products. Three-quarters of the business was done on three of the items. Low profits on the gross sales led this concern to install modern cost methods by which profit and loss was developed by lines. Seven of the items, including the three best sellers, each netted a loss; three which were only moderately popular with the management and customers showed a slight profit, and the four items which nobody in the concern loved made up the losses of their ten brothers and returned the slight net profit which the concern made as a whole. With these definite facts in hand, the management discontinued five of the lines, raised the prices on two, declined to sell three unless in assortments with more profitable items, and pushed the sales of the profitable ones. On total gross sales only half as great as before the net profit was increased 450 per cent. And this in a competitive market where war inflation was not a factor.

One cannot rigidly classify any phase of business and say, "This is a marketing problem," or "This has to do with production alone," or "Leave this to the bankers; it is in the realm of finance." Business is not so simple as that. Often the method of attacking a problem as a simple thing without ramifications results in policies damaging to profits. In the instance just given, we found that wrong selling was caused by wrong cost accounting.

So, as a starter toward sound and economical marketing, I earnestly recommend correct accounting of the cost of manufacturing.

INEFFICIENCIES ELIMINATED BY CORRECT COST ACCOUNTING

Correct cost accounting will not only show in which lines profits lie; it will often indicate manufacturing inefficiencies which, when removed, will leave a satisfactory profit.

I recall one little-known concern which, as a result of accurate cost finding, not only relegated its best seller to the ranks but promoted one of its unimportant products to the vacancy, with the result that the concern has become not only highly profitable but known throughout the world as the maker of the once little-thought-of product. This was a result of the cost system showing gross inefficiencies in the manufacture of the unimportant and little sold product. When the inefficiencies were corrected, it became possible to reduce the selling price so drastically that the product became purchasable by many people to whom it had previously been out of reach. At its lower price, it has become practically a universal necessity.

"Well bought is half sold" is an axiom in merchandising; "well made is half sold" is no less true in manufacturing. Low price for good quality is an argument that needs no high-priced salesman to get across.

SELLING POLICIES DICTATED BY COST CONTROL

High selling costs caused by great difficulty in selling indicate either that effort is being wasted in attempting to sell a product unadapted to the market, for which no need is felt, or that poor manufacturing makes the selling price too high. In the first case the concern had best look around for a product that the public wants—if redesign will not fit it to the market. If the selling price makes the product difficult to sell, the manufacturing methods had best be studied in an attempt to reduce costs. Here a cost system will be of help in two ways: First, by showing just where inefficiencies exist. Second, if the cost methods are modern, they will indicate the extent to which costs will fall as a result of increased production. With this knowledge the manufacturer can set a selling price which may be actually lower than his present cost of production, but which he knows definitely will quickly sell so much of his product that with the increased production will come lowered costs and a satisfactory profit. This is of value not only in settling upon permanent selling policies but also for temporary use in stimulating sales in times of business depression.

ANALYSIS OF SELLING COST

Much of what I have said so far will to many thoughtful readers seem like emphasizing the obvious; that I have stressed the elementary principles of marketing. That is true, yet it is exactly in violations of first principles that many of the selling wastes occur. But

I am going now to describe something not quite so obvious. It is a recent development in cost accounting, which has nothing to do with manufacturing but which dissects selling expenses and indicates plainly wrong policies and wastes which are strictly of a selling nature.

It is, I believe, nearly universal practice to state the selling cost for the business as a whole as a percentage of the total year's sales. That is, with gross sales of \$2,000,000 and a selling expense of \$300,000, to call the selling expense 15 per cent, which for the whole business it of course is. But it is also customary to assume that the same percentage applies for each sales district and for each individual deal. If 15 per cent selling expense leaves a profit of, say, 10 per cent, it is easy to figure that so long as the total selling expense remains at 15 per cent, all sales, all customers and all territories are profitable, and if for the entire business the selling expense jumps to 30 per cent, it is assumed that all sales are made at a loss. Now suppose that a warm old friend of the company strolls into the office some day and gives us his customary spring order for \$10,000 worth of our product. Did it cost us \$1,500 to make that sale? Or take a small finicky buyer at the end of a 125-mile branch line out in Nevada on whom our salesman spends an entire day six times a year and who total orders in that time amount to \$500. Does it cost only \$75 to have him for a customer? Do we make a profit on his business?

The first man is so profitable that he is bound to be the target of all of our competitors. Some day, if we don't watch out, a competitor will make it worth his while to transfer his patronage. The other customer is probably not profitable and unless he can be developed we would be better off without him. But the books of most concerns are littered with accounts like his. He furnishes one of the greatest wastes in industry, which springs from the unreasoning effort to get an increasing volume of sales.

EXPENSE ACCOUNTING FOR EACH CUSTOMER

The idea that increased volume of sales necessarily means increased profits is a natural deduction from the percentage method of figuring selling expense. But it actually costs more and more to "comb" a territory thoroughly.

I have seen concerns make a good profit so long as they confined themselves to skimming the cream from the market, and go broke when they went out to get all the business in sight. Of course, someone must sell the small fellows in the out-of-the-way towns; I don't condemn selling to them. But I insist that some manufacturers are organized to do it at a profit while others are not. The buyer who would be unprofitable to one might well be profitable to another.

The first step is to find out just what it normally costs to have a salesman make a call on a customer or prospect. This normal cost per call will likely be different for each business, perhaps for each territory. In territories where customers are thick and towns close together, it may be low; in the Western States it will undoubtedly be high.

I recommend that an expense account be opened for each customer. Here he is debited with all calls made upon him at the normal cost per call, which, let us say, is \$10. He is also charged with any other expense such as advertising, or the freight on returned goods. He is credited with the net manufacturing profit on the goods

sold him. This gives us an accurate line on how profitable each customer is to us, and the cause for the loss if he is not. He may require an undue number of calls to straighten out kicks; he may buy principally those lines which carry a narrow profit; he may have the habit of rejecting shipments; for any one of a dozen reasons his trade may be unprofitable.

Since we know just why he is unprofitable we may be able to educate him into a profitable customer or he may be so hopeless that we would do better to drop him. Or there may be reasons of policy for retaining him, even though he is hopelessly unprofitable. In any event our actions are not based on a false idea of what it costs to sell.

TERRITORIAL SELLING COST ANALYSIS

A report which is of value is the territorial analysis. In the upper part of this we gather all of the items of selling properly chargeable to the territory, which includes the direct items such as salesmen's salaries and expenses, branch office expense and those indirect charges made up of share of general sales expenses, share of advertising, share of clerical expense and so on. The shares are not based on the volume of business. The method of distribution of selling cost is different for nearly every business. Take the general sales expense, for instance. If the sales manager spends most of his effort supervising salesmen, the number of salesmen in a territory would be the fair measure of how much of his salary should be charged to each territory. If, however, the sales manager is occupied with the solution of sales problems, it is usually best to have him keep an approximate record of the time he devotes to the problems of each territory and to distribute the

expense on that basis. A different method is used to determine the shares of clerical effort; and still another to determine how much of the advertising expense is chargeable to each territory. In this way, we build up the total selling expense by territories.

At the bottom of the sheet we note the number of calls made and extend it by the normal cost per call. Comparing this figure with the total actual expense shows whether the territory cost more or less than normal. If more, the cause may be either a reduced number of calls or extravagance on one or more items of expense. We divide the total calls made into those made on customers and those made on prospects. This gives us the amount of money spent in developing new business. We may even determine upon a proper proportion of the total expense which should be spent in development.

A supplementary report may well be used on which we list all customers and the net profit on each. From this we deduct the total by which the selling expense of all territories exceeds normal, and to it we add the amount by which all territories are below normal. This gives a figure from which is deducted the amount spent on sales development to give the net profit.

These reports properly devised to suit the needs of the individual business will analyze thoroughly the selling expense—show where the effort is good and where poor. The reports will not of themselves make profits; but they will give accurate data to the management on which they can build profit-making policies. They will help dispel the fog that has always hung over selling, and by indicating what the wastes are, will show how they may be eliminated.

Wastes in Litigation

Losses Arising From Litigation a Potential Factor in the Success or Failure of Any Industry or Business
—Lack of Knowledge of Technical Terms and Standards on the Part of the Courts a Strong
Argument for the Establishment of Arbitration Courts Within the Industry

BY WELLINGTON GUSTIN

Member of the Chicago Bar

THE average business man, upon going into business, at least in the past, has never figured on the probable losses that may arise from necessary litigation. This is a factor that cuts down profits, if it does not entirely destroy them, in nearly every business enterprise. Insurance against losses by litigation has not yet developed, though perhaps it is as certain a loss as that arising from credits, which are now being insured, or from other contingencies no more certain to happen.

But a very potential factor for harm and loss to any industry or business is possible litigation. It has put many a promising enterprise on the rocks. Anything from total disruption of business to a destruction of all expected profits on a contract may result from disputes ending in the courts. When men cannot agree the courts are necessary as a final arbiter, and it is not intended to lead any reader to take any statement herein as derogatory of the courts of justice. They are the bulwarks of our rights, our liberty and our civilization. But a broader intelligence will admit and encourage business men especially to take every reasonable step to prevent litigation. Here the ounce of prevention adage holds true, as almost any litigant will testify.

CHEMICAL INDUSTRY OFFERS WIDE LATITUDE FOR LITIGATION

In the chemical industry there is the widest possible latitude and opening from which claims and court actions may develop. In the manufacture and sale of chemicals and chemical products the specifications may be open to attack because lacking in certainty between the parties, because there may be no definite or known standard by which the parties may contract and to which they may refer to settle their disputes outside of court. An accepted authority, or standard known and accepted by the industry, would be a big step forward in the interests of the industry as well as the individual members composing it.

As the industry now stands a court, through its judge or jury, must pass upon the scientific and intricate questions of quality or other properties of chemicals, etc., which may happen to be in dispute between buyer or seller. And mayhap, to prove his case, a litigant will be required to bring in all the knowledge of the industry on the particular products in question as well as the customs and usages of the trade. Then all this will have to be done over again should a similar situation arise in litigation. This results in involved expense on every litigant.

There is another feature to be considered, and that is that after a case is litigated whether the correct results have been obtained and justice done; whether it would not be more satisfactory to the trade for men educated and trained and learned in the business to

pass upon and decide questions of fact of which they have a peculiar and particular knowledge than to permit of these questions being decided by judges and juries unlearned in the particular field of science and fact being investigated.

MUTUAL MISTAKES IN LANGUAGE OF CONTRACT

Sometimes a party to a contract contends that the language used and as interpreted by the other party does not express the "mutual" meaning of the parties. Whether it does or does not presents a serious question of fact that might be obviated or precluded by a recognized standard. The remedy of the complaining party is to go into a court of equity and have the contract corrected on the grounds of mistake of fact on the part of both parties. One can appreciate the difficulty encountered should the other party to such a contract deny there was a mutual mistake. In the ordinary case, the costs of such a proceeding and the obstacles to obtain proper evidence and make proof to show that language used in the contract did not express the mutual meaning of the parties are so great that justice is not had; and only when large amounts are involved and the litigants have sufficient resources to litigate and perhaps pay fees to scientific experts in the chemical industry may the true facts and a proper construction of certain agreements be arrived at.

Now when it is contended that the words of the contract do not express the mutual meaning of the parties, what may we, in the chemical industry, refer to as a standard? Have we anything definite and certain that will conclude these matters—prevent the use of the wrong words, or that will give such meaning and standard to the technical words of the science and industry, designating the standards of chemicals manufactured, sold and used commercially or otherwise, to prevent the claims that may arise out of the meaning of the contract in these respects?

LANGUAGE OF CONTRACT CONSTRUED BY COURT

Should an instrument of agreement contain language which, when it is sought to apply it to the subject matter of the contract, becomes ambiguous, a court is required, when the case is brought before it for a decision, to look to the facts and conduct of the parties, the surrounding circumstances bearing on the transaction, etc., to ascertain the sense in which it was mutually used. And the court's decision would rest on the facts shown to it that the language used could be given no other meaning than that contended for by the party who set up the claim of mistake in the contract.

If the language in an instrument, say an order or contract to manufacture and sell, is susceptible of more than one meaning, the parties are bound by the sense in which it was mutually used. But proving this point

presents, ordinarily, a legal issue, a fight in the courts. Recognized standards, accepted and approved in the chemical trades and industries, would in the main wipe out litigation of this kind. Certainty of this kind would first prevent any honest mistake in meaning of the parties at the time they enter into any arrangement, and it would prevent dishonest parties, for an advantage gained, later to set up a claim of mistake of meaning.

With regard to the meaning of words as used by parties in expressing their agreements, the popular or common standard controls on the face of things, but such is always open for proof to the contrary. Where a word or phrase is ambiguous, but was used and accepted by both parties to a contract in undertaking to express in writing the terms of the agreement actually made, they thereby have set up a mutual standard of their own and will be bound thereby. But such offers ground for litigation. The rule as to mutual standards in most states is subject to the modification that a clear and unambiguous meaning will not be overthrown by resort to oral or outside evidence to determine what the parties actually intended. (See Wigmore on Evidence, vol. 4, page 3475.)

Of the great mass of litigation clogging the courts throughout the country, only a small number comparatively reach the courts of appeal. Following are cases that have been brought up from the trial courts to appellate courts and often to the courts of last resort, where in some instances the litigation is finally and fully determined, while in others the cases are remanded and sent back to the original trial courts where the machinery of the courts is again set in motion—perhaps to be continued up by appeal or other proper procedure to the courts of last resort again.

The cases selected are those touching upon the quality, properties or specifications of the products, showing where a lack of standard makes it impossible not only to know in advance what is being bought and sold but prevents buyer and seller from referring to an accepted authority to settle their disputes.

LACK OF STANDARDS CAUSES PATENT LITIGATION

Lack of standards enters into the inventive or patent litigation. An inventor describing his process and stating his claims names the chemicals employed, agents and factors used in producing a result. Others exploring along the same or similar lines are not informed by the patent with such precision as to steer them clear of the process patented. Employing chemicals as called for by the patent, they do not obtain the results claimed, and proceed in a search to improve the process or discover a true solution. In one noted case a learned scientist testified that he used the chemical factors called for by a process patent, but did not obtain the product of the inventor. He had used chemicals with certain impurities, according to the testimony of other scientists who had obtained the desired results with chemicals of a different standard. (*Matheson vs. Campbell*, 69 Fed., 597.)

This lack of proper standards for chemicals confused the users of the patent and there developed a useless competition and infringement. By making certain tests of the chemicals employed and using only those up to a certain necessary requirement or standard, the users of this process testified, they obtained the product of the patent. Those using the same chemicals in kind but of a different standard of purity were misled by the patent

claims, and believed that they were untenable. Here the court held that the use of "nitrate" of sodium for "nitrite" of sodium in the specifications of a patent relating to the manufacture of a coloring compound from coal-tar products was not such a misuse of terms as would invalidate the patent; it appearing that no one skilled in the art would be misled thereby and that the use of "nitrate" for "nitrite" was common in the earlier patents relating to the particular art. Here, too, the court defined "chemically pure" to mean absolutely pure, and "technically pure" as used in reference to substances employed in chemical processes to mean pure in the ordinary acceptance of the terms of the art.

RIGHT TO INSPECT GOODS BEFORE ACCEPTANCE

The case of the Imperial Products Co., Inc., vs. Capital Chemical Co. involved the question of inspection of the product sold (176 N. Y. S., 49). The buyer of the product demanded the right to inspect the goods upon delivery and before payment. In such a case with known standards and an agreement based thereon, the matter of delivery would ordinarily be of small moment, as an acceptance of delivery could not be shown to establish the quality of the product or be taken as an acknowledgment that it conformed to the specifications or other descriptions of the agreement.

The law involved in this case is to the effect that under the personal property statute of New York a buyer is entitled to inspection of goods purchased, before delivery and acceptance, unless there are terms to the contrary; that a carrier of the goods is bound to permit of this inspection unless the sales agreement is that shipment should be made "collect on delivery."

Under the New York law, where no terms of payment are specified delivery and payment are concurrent obligations, and the buyer has the right of inspection to ascertain whether the goods are in conformity with the contract, when the seller tenders delivery, before he is required to accept and pay for the goods. But the court says this is very different from payment of the purchase price by sight draft with bill of lading attached. Here payment is a condition precedent to delivery and hence inconsistent with the right of inspection.

SELLER LIABLE WHEN HIS GOODS RUIN PRODUCTS MANUFACTURED BY THEM

In the case of James K. Thompson Co., Inc., vs. International Compositions Co., Inc. (181 N. Y. S., 637), the Thompson company brought suit to recover the purchase price of a quantity of copper oxide. The amount contracted to be sold was 11,862 lb., which at 33c. a lb. amounted to \$3,914.66. There were three deliveries of this oxide. After the third delivery the defendant returned 2,907 lb. and the plaintiff, Thompson company, received it and gave defendant a credit therefor. The balance due for the oxide not returned and accepted was \$2,955.15, and plaintiff recovered a judgment for this sum.

On appeal the Appellate Division of the New York Supreme Court reversed the judgment and granted a new trial. It appears that the copper oxide was sold for a specific purpose—for making a high-grade anti-fouling marine paint. It was admitted that the first two deliveries of the oxide were up to the standard required by the defendant. But there was evidence to show that the third delivery was not up to the standard required by the paint manufacturer and not in conformity with

requirements of the contract and with the standard of article known by the seller to be necessary for the buyer's uses. Before discovering the defect in this article, however, the buyer had used a part of the third shipment, and in making paints therefrom, it made paint which was utterly useless and which was returned by its patrons, and the buyer claimed to have suffered damages by reason of the loss of other materials that were used in the paints, which were then rendered unsalable by reason of this defective copper oxide. Therefore against the seller's total claim for oxide delivered the buyer set up a counterclaim for damages thus suffered in the amount of \$5,267.66.

In defining the rules of law which govern the plaintiff's right to recover the court said that if the plaintiff had knowledge that the defendant required a certain quality of copper oxide for the use of the paint as it was manufactured, then it was bound to furnish that quality under the contract, and that the burden of proof was upon it to show that quality was furnished. On the counterclaim of defendant the court stated that the defendant had the burden of proof, in establishing its counterclaim, to prove that the goods were not of the quality required by the contract, and required by the knowledge that the seller had of the buyer's requirements and the damages that were suffered therefrom.

ADVANTAGE OF HAVING KNOWN STANDARDS

In the case of *E. I. du Pont de Nemours & Co. vs. Robinson & Son*, 204 Ill. App., 529, an advantage of having known standards and quality is presented. Here it was held that although the buyer was given opportunity to examine the product delivered and although it was subsequently used by the buyer, such did not constitute an admission by the buyer that the quality of the product was satisfactory and that it conformed to the contract. For, under the facts in this case, a mere examination by the buyer of the boxes and their contents would not necessarily inform the buyer of the quality of the product, says the court. But where may the complaining party go for proof of what he bought? To his contract. But to what standard and what reference may each of them go in case of dispute as to contract, or better still, in drawing up the contract in regard thereto?

BUYER'S RIGHT TO A PARTICULAR BRAND ORDERED

Of course no standards or other precautionary acts of parties entering into a contract may prevent frivolous defenses and claims being made where litigants are so disposed to fight. All that this forward step can do would be to reduce the difficulties to a minimum and make the results of a suit in equity or an action at law more certain, with the facts or evidence and the proper benefits available to the rightful party or parties.

Again, where one contracts for a particular brand of product he is legally entitled to the brand, though the standard is the same as another substituted. In the case of *Coff-Garrod Co., Inc., vs. Dodwell & Co., Ltd.*, there was a contract for the sale of Monsanto or Heyden brand saccharin of a specified grade or standard. The product was sent in boxes of the American Condiments Co., a subsidiary company of Heyden Chemical Co. The evidence was that the parties were contracting for goods of a certain character and quality, and not labels, and that "Heyden brand" and "Heyden make" of saccharin meant the same thing. Therefore, since the complaining

party obtained a product of the standard contracted for and of the proper manufacture he could not set up a defense of improper trademark or brand. (170 N. Y. S., 615.)

SALE BY DESCRIPTION CANNOT BE TRANSFORMED INTO A SALE BY SAMPLE

In the case of *American Aniline Products, Inc., vs. Mitsui & Co., Ltd.*, there were three sales contracts for dyes for export. The buyer claimed samples of dyes were submitted with the offer of sale, and it was agreed deliveries of dyes under orders would be equal in quality, strength and all other respects to the samples submitted. The orders showed a sale by description, being "Amacid Blue Black K N" and the court said the obligation of the seller was merely to deliver goods to that description of merchantable quality. To attempt to transform a sale by description into one by sample is to attempt to vary the obligation of the seller as to the quality of the article to be delivered, which could not be done. And the evidence as to the sample submitted prior to giving the written orders was not admitted in the case. However, the court held that upon trial either party would be at liberty to define by word of mouth the term "Amacid Blue Black K N." Such evidence does not vary the meaning of the writing, but discloses the full meaning of the parties. The Supreme Court of New York and the Appellate Division were called upon to decide these points.

DELIVERY OF ONE GRADE WHEN BUYER THOUGHT HE CONTRACTED FOR HIGHER GRADE

In the case of the *Independent Trading Co., Inc., vs. E. Fougere & Co., Inc.* (183 N. Y. S., 431), plaintiff brought an action to recover damages for alleged breaches of written contracts for the sale of potassium guaiacol sulphonate, c.p., white. Defendant admitted the contracts but defended on the ground that it never understood that it was agreeing to deliver to the plaintiff the quality of the chemical called for in the contract and which plaintiff claims the defendant agreed to deliver. Upon trial the sole question presented was of a mutual mistake respecting the identity of the article in suit.

Upon this proposition it was claimed that there were two grades of potassium guaiacol sulphonate recognized by the trade. One of these grades was claimed to be in powder form, known as calcine, the other being a crystalline form of perfectly white crystals. The calcine was at time of the sale of the value of \$10 per lb. and the crystalline form was of the value of about \$30 per lb.

The seller understood that the article called for by the contract was the calcine or powdered form then being sold as the commercial product. This product was being manufactured by the Lister Chemical Co. It was not the same article called for in the contract. On the part of the seller it was shown that another product known as "thiocol" was on the market, which contained the same chemical ingredients as potassium guaiacol sulphonate. Thiocol, however, was a trade name belonging to its manufacturers, the Hoffman-LaRoche Co. And the testimony for the seller that it had sold the cheaper article, and that it was customary to use the term "thiocol" or the term "crystal white" in describing the crystalline form was not supported.

In its opinion the court says it is convinced that no mistake was made by either party; that the seller was endeavoring to sell to the trade an inferior product and

deliberately intended to deliver, under the contract, an article known to be inferior; and the seller, having made the contract in question which used the terms well understood in the trade, should be held to a strict performance thereof.

On the question of mutual mistake as to the identity of the product in suit, the court said even though the evidence supported the seller's claim that it did not understand the effect of the contracts which it made, and did not know that it thereby agreed to sell and deliver the crystalline form of the commodity, there was no mistake on the part of the purchaser. It knew what it wanted and what it bargained for—namely, "potassium guaiacol sulphonate, chemically pure, white." What this product was, as established by the trade, could not be denied by the seller.

A standard and knowledge in the trade as to the product in dispute dispensed with the more intricate questions that might have arisen had there been no standards for reference and proof. Putting over an inferior product, as the majority believed was attempted here, might become an easy matter with unscrupulous dealers.

QUALITY OF STEEL QUESTION FOR JURY

In the case of Griffin et al. vs. Metal Product Co. (107 A., 713) defendant purchased from plaintiff certain high-speed steel. The buyer acknowledged receipt of the steel, that it appeared to be in good condition, but alleged that upon use it was valuable only as scrap steel. The question as to the quality of the product was presented to the jurors, who decided from the evidence that the steel was high-speed steel and gave judgment for the defendant buyer. But the Supreme Court of Pennsylvania has reversed this judgment and granted the defendant a new trial.

Under the uniform sales act providing that on sale of an article under its patent or other trade name there is no implied warranty as to its fitness for any particular purpose, a "trade name" is a name given by a manufacturer to the particular product made by him, and the generic name of an article made by several is not a trade name. The Supreme Court holds that speed-steel is not a trade name but a name common in the trade and where sold for use by the buyer for a use known to the seller there is an implied warranty of quality suitable for the purposes intended.

KIND OF GOODS DELIVERED A QUESTION FOR JURY

In the case of Samuel and others vs. the Delaware River Steel Co. (107 A., 700) the Supreme Court of Pennsylvania said the kind of goods delivered under the sales contract was a question for the jury to determine from the evidence submitted. There was an appeal in this matter from the trial court to the Pennsylvania Superior Court, thence to the Supreme Court, where it was finally remitted to the Court of Common Pleas for a new trial.

It appears that the defendant purchased from the plaintiffs, brokers in steel and iron products, two carloads of a commodity known to the trade as "roll scale." Upon unloading the material the Steel company discovered, as it alleged, that the contents of one of the two cars contained largely mill cinder, a product of less value than roll scale. The buyer used the product in dispute, but refused to pay on the basis quoted for roll scale. The seller contended the product delivered was

roll scale, and further, that if it were not such product, the buyer, by accepting and using the product, waived the right to object that it was not the article ordered.

INTENTION OF PARTIES DETERMINE—WHERE AMBIGUOUS WORDS ARE AGAINST PARTY USING

In the case of Fletcher vs. Interstate Chemical Co., the question was the construction of the contract. (110 A., 709.) The Supreme Court of New Jersey here said the cardinal rule in the construction of all contracts, sales included, is that the court must, if possible, ascertain and give effect to the mutual intention of the parties, as far as that may be done without the violation of legal principles. And where a contract is ambiguous it will be construed most strongly against the party preparing it or employing the words concerning which doubt arises. This case was appealed from a judgment of the trial court to the Supreme Court, where judgment against defendant was affirmed.

STRICT READING OF CONTRACT ENFORCED

In the case of Filling Machine Co. vs. United Smelting & Aluminum Co. (107 A., 619) the sole question involved was whether "rod aluminum" meant pure aluminum. The jury in the case was instructed by the trial judge to determine whether the words in the order given "to be drawn to our specifications" had any distinct well-known meaning in the trade, applied to both size and composition or to size only, and whether plaintiff knew or ought to have known that the words were used in such special sense. On appeal this instruction to the jury was held error by the Supreme Court of Errors of Connecticut.

This court said the sale being of specific goods designated as "rod aluminum" in the written contract as completed and in the written negotiations leading up to the contract, it was the duty of the seller to furnish "rod aluminum" as that term was ordinarily used in the trade.

GOODS MUST BE SUITABLE FOR USES REQUIRED

In the action by Smith, DeMacedo & Co., Inc., vs. Swift & Co. (110 Atlantic, 141) it appears that Swift & Co. sold the plaintiffs 34 tons of oleo-stearine which was represented to be suitable for the same purposes or uses and to comply with the specifications set forth for stearic acid. This product was to be resold and exported to Portugal for use there. Upon arrival there it was found that the article did not conform to specifications, the plaintiff's customer declined to accept the shipment, and it was necessary because of shipping conditions to sell the product in Lisbon at a loss to the best bidder.

Smith, DeMacedo & Co., Inc., brought suit to recover damages for failure to deliver goods answering the warranty that they would be suitable for the uses required. This case was carried to the Supreme Court of Pennsylvania and a judgment for the plaintiff was sustained.

REPRESENTATIONS BY SELLER AMOUNT TO WARRANTY

In the case of Swift & Co. vs. Meekins et al. plaintiff sued to recover for the price of fertilizer and acid phosphate. Defendants set up a counterclaim for breach of warranty as to quality of the fertilizer. The sale consisted of 10 tons of acid phosphate and 40 tons of fertilizer analyzing 5-7-0. Meekins testified that

sellers' agent, at time of the sale, stated the fertilizer was as good as any of the same analysis sold to be used for cotton and corn and was as good as any on the market. The case was carried from the trial court to the Supreme Court of North Carolina when the court held these statements amounted to a warranty in law. The positive representation, without any intention to deceive, by a seller that the article sold possesses a certain value and certain qualities amounts to a warranty and the purchaser may set up the breach of warranty to reduce the sum claimed.

GOODS NOT UP TO SPECIFICATIONS

In the case of Grasselli Chemical Co. vs. City Ice Co. (75 So., 920) action was brought to recover the price of certain shipments of anhydrous and aqua ammonia. Defendant claimed that plaintiff warranted all anhydrous ammonia perfectly pure and dry and all aqua ammonia sold to be absolutely 26 deg. aqua ammonia, which warranty was breached, causing a resulting damage to it of \$7,500. The Chemical company contended that it sold all of the ammonia by description only; that the aqua ammonia was sold as 26 deg. at 60 deg. F., and was merchantable; that the anhydrous ammonia was merchantable dry anhydrous ammonia; and each was so warranted. It further charged that defendant's trouble in its use of the product was due to its machines and not to the chemicals employed. An adverse judgment was rendered against the Chemical company and it appealed to the Supreme Court of Alabama, where the judgment was affirmed.

CONTRACT PROVIDING FOR SETTLEMENT OF DISPUTES

The case of Home Guano Co. vs. International Agricultural Corporation involves the sale of 21,600 tons of sulphuric acid. This case was decided by the Supreme Court of Alabama. (85 So., 713.) While there is no controversy over the quality, kind or properties of the goods sold, the contract covers these matters so well that it is given here. Contracts are usually loosely drawn, and never cause any difficulty as long as both parties are satisfied in their dealings, but when dissatisfaction crops up the terms and provisions of the contract become important. The contract provisions here given show how the parties provided for disputes as to the product sold:

"It is understood that seller is privileged to deliver acid of greater or lesser strength than 60 degree Bé., but not less than 57 degree Bé. nor more than 62.50 degree Bé. For any excess in such acid above or below 60 degree Bé. a proportionate reduction shall be made in the price per ton according to the per cent of 60 degree acid contained in such acid of higher or lower degree, as set forth in the table of the Manufacturing Chemists' Association. Approximately at the end of each month seller shall reimburse buyer for additional freight which buyer may have paid or incurred liability for by reason of the shipment of acid of weaker strength than 60 degree Bé., and buyer shall pay to the seller the amount of freight charges saved to the buyer by reason of the shipment of acid of greater strength than 60 degree Bé. Settlement shall be made for each and every shipment upon the basis of 60 degree Bé., as determined by the producing company, at Copperhill, Tenn., whose test shall be the basis of the settlement. In case of dispute as to the accuracy of such analysis, sample of the carload in question, as

drawn by the producing company at Copperhill, shall be submitted to analytical chemists, Ledoux & Co., 99 John St. New York, for analysis, whose determination shall be final."

HOW STANDARDS MAY BE ESTABLISHED

In Penn Steel Castings Co. vs. Wilmington Malleable Iron Co. (41 A., 236) wherever an order was to be carried out with quality "up to standard" it became necessary to prove the standard. In attempting to define the contract meaning of the term the court says a standard implies a measure or test which has the general concurrence and recognition of the class of persons engaged in the particular business or trade under consideration.

Now long and continued usage may develop and determine standards in any field. Considering how long-established and widely known has been the particular business involved in the steel industry, the court thought it was not unreasonable for it to presume, until the contrary be shown, that some well-known standard was generally recognized in that business or trade.

Thus standards may grow slowly through a mass and haze of difficulties with all the attending losses and lessons of experience, or they may proceed in an orderly march, being established in an exact and scientific manner, agreed upon in advance, recognized and approved by the trade.

All these transactions and matters are affected through the factor of evidence in controversies or disputes. When parties dispute the facts, dispute the quality or properties of the subject of contract agreement, where shall they go for aid? What is the mean or standard of measurement that may be brought in to determine the truth and facts in the evidence? What, itself, may be the evidence? With established standards the facts and truth as to matters in evidence may be readily arrived at in a manner satisfactory to all concerned, preventing at the same time dishonest transactions which are now possible.

ADVANTAGES OF ARBITRATION LAWS

Some states have enacted what is known as an arbitration law, notably New York and Illinois. These laws offer much promise to business men, but, being a new departure, have not been availed of to any great extent.

Where contracts contain the proper provisions for arbitration of the differences arising thereunder, in states having these laws it appears that the quality of products and other similar grounds of dispute may be more readily determined, the facts more properly found by referring to an arbitrator or a board of arbitrators—all skilled or educated in the field of inquiry.

I am of the opinion that many of the difficult questions arising in the chemical and allied industries can best be met by an acceptance of such new laws as offer the opportunity of arbitration in disputes and by making use of them. This last is a very necessary and vital thing—the making use of the principle. Skilled and experienced men should be designated as arbitrators, perhaps by the various industries in advance, to whom parties to a contract may look in case of disputes arising. Boards of arbitrators may, in the future, take the place of and do much of the work of courts, unlearned in the particular fields of inquiry. But arbitration will require no little effort for its firm establishment.

Chicago, Ill.

Eliminating Waste and Nuisance in Smoke, Fume and Gas

Suppression of Industrial Waste Byproducts Is Essential Not Only to Avoid Economic Loss but to Abate Nuisance in Residential Localities—Methods Originally Developed for Metallurgical Processes Find Application in a Wide Variety of Industries

By P. E. LANDOLT

Chemical Engineer, Research Corporation

WITH the rapid growth of industry in the past twenty years, we have been confronted with the necessity of waste elimination for conservation or as a public necessity. Waste elimination is truly economic, benefiting industry directly in many cases and ultimately the public. A phase of the industrial waste and nuisance problem that has had a pronounced effect on the industries and the surrounding localities is that of so-called smoke nuisance. In some instances it was allowed to increase to a point where local damage was extreme, and later during its abatement many interferences and delays to industries resulted. Frequent abandonment of large industrial plants followed, and the economic losses, both public and private, were very great. Much of the smoke nuisance has been tolerated or ignored by the public, either accepted as inevitable or essential to industry. Moreover, it has been borne with sullen indifference or accepted as a commonplace like the weather, etc.

SOLUTION IN NO ONE METHOD

The solution of these problems of smoke nuisance or air pollution cannot be effected by any one method, because our industries are essential to the progress of civilization, and therefore careful consideration must be given to every phase of any one problem to be certain that real improvement has been made. If other wastes as great in magnitude as the original one result, then nothing has been gained. All of these problems, therefore, require broad treatment by industrial specialists and by engineers, so that the benefits obtained may be of lasting value.

Prevention is a first consideration; but frequently it is found quite impossible, at least impractical, to prevent such loss or nuisance due to waste gases. Sometimes it is found desirable to carry off materials in waste gas currents and recover such materials later, separated from other materials with which they were originally associated. Moreover, after such materials are removed from a gas, it may be useful for other purposes where it would be useless if not free of such suspended matter.

Many schemes have been used for the removal of suspended matter from gases and under certain conditions have proved satisfactory. In general these consist of mechanical devices for settling dust by gravitation, centrifugal action, baffling or change in gas velocity; washing with water or other liquids, as a fine spray or over packed towers; filtering by means of cloth bags, screens or layers of finely divided or fibrous substances. All of these methods have fairly well-defined limitations, such as temperature, corrosion, power requirements, replacement costs; the quantity and composition, both physical and chemical, of the

material to be removed; water consumption or disposal of the collected material.

ELECTRICAL PRECIPITATION

The development of electrical science has added to the foregoing another method—namely, electrical precipitation—which has been developed commercially during the past fifteen years, and which has been shown to have a wide range of practical operation, particularly where corrosion and high temperature are factors or large-volume treatments are essential. The equipment required for the operation of the Cottrell electrical precipitation processes has been gradually standardized to make these processes readily adaptable to a wide range of industrial problems. The monetary value of metallurgical smoke recovery, for example, has been tremendous, but the resultant applications developed constantly increase the field of usefulness of these processes and promise even greater value in the future as an essential part of other new processes and industries.* The diversity of these applications is shown by the following summary:

I. Non-ferrous Metallurgical Fume and Dust: Recovery of copper, lead, tin, zinc, silver, gold, bismuth, etc. Operations: Sintering machines, reverberatory furnaces, blast furnaces, converters, roasters, driers, etc.

II. Acid Problems: *a.* Sulphuric acid—concentrators (new, spent and sludge acid), parting kettles. *b.* Nitric acid—nitrating operations. Phosphoric acid—phosphate rock reduction. Hydrochloric acid—roasting operations, pickling, etc. *c.* Miscellaneous—Recovery of chlorine, bromine, etc.

III. Smoke, Soot and Cinder: *a.* Boiler plant gases. *b.* Engine roundhouses. *c.* Lamp black from oil. Carbon black from natural gas.

IV. Cleaning of Gases Containing Sulphur Dioxide: *a.* Hot gas (pyrite burners)—sulphuric acid manufacture. *b.* Cold gas (pyrite burners)—sulphuric acid manufacture; (sulphur burners)—sulphite liquor production.

V. Combustible Gas Cleaning: *a.* Iron blast-furnace gas cleaning. *b.* Hot producer-gas cleaning. *c.* Tar recovery from producers, illuminating gas, coke ovens, low-temperature carbonization (fractionation), wood distillation.

VI. Air Cleaning: *a.* Small capacity installations—foundries, machine rooms, etc. *b.* Large volume installations—slate crushing, etc.

VII. Miscellaneous Applications: *a.* Dust and fume from industrial operations: 1. Potash from cement

*For the purpose of this presentation no direct reference will be made to the theory and description of these processes. For complete details of same the reader is referred to the selected bibliography at the end of this paper.

kilns. 2. Large electric furnaces. *b.* Dust and fume from miscellaneous chemical plant operations. *c.* Organic materials—spray drying, milk, fruit juices, etc.

IN THE METALLURGICAL INDUSTRIES

The metallurgical industries have contributed most largely, if not entirely, to the commercial development of these processes. The early efforts of Sir Oliver Lodge in England, Dr. Moeller in Germany and Dr. F. G. Cottrell in the United States led to final accomplishment. Dr. Cottrell was greatly aided in his early work by the co-operation of local industries, primarily E. I. du Pont de Nemours & Co., at Pinole, Cal., and the Selby Smelting & Lead Co. at Vallejo Junction, San Francisco Bay.

Copper Industry.—Many large copper-smelting plants have been equipped with Cottrell precipitators, making recoveries of copper, silver, gold, zinc, lead, arsenic, etc., that have paid from 15 to 50 per cent net per annum on the installation investment after deducting all operating charges, depreciation, interest, repairs, etc. In addition all damage to the surrounding country has been eliminated or minimized. The total investment in Cottrell installations in copper smelters is approximately \$5,000,000, and with a net return on investment of 20 per cent on such installations, this represents a net saving in copper alone of at least 5,000,000 lb. per annum, and a total of at least 8,000,000

FIG. 1. ELECTRICAL PRECIPITATOR FOR RECOVERING LEAD, TIN AND ZINC FUMES FROM REVERBERATORY FURNACES HANDLING DROSSES

cu.ft. of gases have been so "treated" per minute (400,000 to 500,000 tons per twenty-four hours).

Lead Smelting.—Many lead-smelting plants have installed Cottrell precipitators, and the net recoveries compare favorably with those in the copper industry. At least \$3,000,000 has been invested in these installations, with a corresponding net saving of at least 15,000,000 to 20,000,000 lb. of lead per annum.

Tin Smelting.—Numerous secondary metal plants and a primary tin smelter have been equipped with Cottrell precipitators and have paid a net return per annum on their investment of at least 50 per cent (in some cases nearly 100 per cent) after making all deductions, fixed charges or operating expenses. The total investment in these installations is nearly \$400,000, and

the consequent net saving is at least 2,000,000 lb. of tin per annum.

Silver Refining.—The large silver refineries (whether from copper- or lead-smelting sources) are equipped with Cottrell installations. The total investment in them is not over \$300,000, but the total recoveries in silver alone are at least 500,000 oz. per annum. Considerable gold is also saved in addition.

IN THE CHEMICAL INDUSTRIES

The development of the chemical industries has given further opportunity for the application of these processes.

Sulphuric Acid.—Sulphuric acid mist is well recognized as difficult to catch by ordinary means. Dr. Cottrell first applied electrical precipitation to sulphuric acid mist and found the mist was "condensed" or precipitated electrically with the greatest ease.

During the war maximum operation of sulphuric acid-concentrating plants made the acid mist nuisance quite pronounced. Various scrubbing devices used were a failure, were impractical, or rendered this recoverable acid a complete loss. Cottrell installations for this purpose during the war period from 1917 to 1919 made an acid saving, besides abating a serious nuisance, of at least 10,000 tons (66 deg. Bé.) acid per annum. Further development of these processes at that time would have avoided far greater wastes.

Applied to the recovery of sludge acid from oil-refining operations in conjunction with approved sludge acid concentrators, more or less recently developed, these processes serve as a useful part of such equipment. The Cottrell precipitator collects practically all of the acid discharged with the waste gases, returning it to the system at an appreciable concentration. The total acid losses in such a combined system are reduced to a minimum. Acid problems usually mean property damage, and even where the plant is isolated the elimination of acid gases is justified for the saving of wear and tear on plant buildings, roofs, products, etc.

Phosphoric Acid.—These processes are being utilized in connection with the direct reduction of phosphate rock in electric or other furnaces. Phosphoric acid is recovered directly and is used to saturate phosphate rock, giving a superphosphate of high P_2O_5 content, saving the use of sulphuric acid and extra freight on the transport of acid or a phosphate product of less value per ton.

ELIMINATION OF SMOKE AND SOOT IN POWER PLANTS

Smoke and soot from large power plants have been decreased in most cases to an almost negligible amount, but an ever-increasing problem of cinder and ash dust being carried out of the stacks is a serious one. The former problem is being solved largely by preventive methods (improved mechanical firing equipment, control of fuels, etc.), but the latter problem of cinder and ash appears to be soluble only by supplementary collection. Here the material collected is almost if not entirely valueless, the gas volumes are very large, and the duty is extremely severe. Such plants, being operated to their maximum ratings, require close draft adjustment and practically no draft interferences. Schemes have been tried and have succeeded to a large extent in improving stack conditions for such power plants. In the main, therefore, Cottrell installations have not been justified for such conditions, but the

development of apparatus for electrically cleaning such gases at very high velocities (2,000 to 3,000 linear feet per minute), together with the development of powdered fuel combustion for power plants, promises to create a real need for such equipment on a basis that will be sound economically.

THE NUISANCE OF THE ENGINE ROUNDHOUSE

The large engine roundhouses in cities present a problem that constitutes a real nuisance. Owing to the corrosive nature of the gases from such roundhouses, washing equipment is costly to install and maintain.

FIG. 2. ELECTRICAL PRECIPITATOR FOR RECOVERING LEAD, TIN AND ZINC FUMES FROM REVERBERATORY SMELTING FURNACES TREATING DROSSES

Electrical cleaning (dry) has been tried and a large installation has been under construction for some time. Unfortunately severe depression in the railroad industry has prevented the completion and operation of this installation. Here, again, the material is of little or no value, but the nuisance is probably not preventable. Earnest efforts have been made by the railroads to minimize such nuisance.

Much has been written on the indirect cost of black smoke nuisance, but for the purposes of this paper a review of all these public "losses" will not be attempted. The reader is referred to official reports of the cities of London and Birmingham, England, and Pittsburgh and Chicago in the United States.

WASTE IN CARBON BLACK AND LAMP BLACK MANUFACTURE

Studies of the smoke and soot ultimately called attention to the problem of waste in carbon black and lamp black manufacture. Present methods of production and recovery are quite inefficient. In carbon black alone less than 1 lb. of black is produced per 1,000 cu.ft., natural gas containing at least 33 lb. carbon in the form of hydrocarbons. These finely divided carbon particles can be readily precipitated electrically, and the electrical precipitator may be readily adapted to conform with other processes devised to increase the yield of such carbon black or lamp black. The next five years should accomplish rather radical changes in this industry, if developments at present under way are ultimately a commercial success. For an equal

production of carbon black the investment saving will be easily one-half, the cost of production per pound will be one-half, and the natural gas consumption one-quarter (or less) of present methods.

ELIMINATION OF WASTE IN SULPHURIC ACID PLANTS

Referring again to the chemical industries, the cleaning of hot sulphur dioxide gases from the roasting of pyrites for the production of sulphuric acid is an example in which the elimination of waste is indirect. The saving in this case is mainly one of labor and maintenance—power also to some extent. In chamber acid plants there would also be a saving of niter. In contact acid plants, cleaning of subsequent equipment would be less frequent. A total saving in production cost of, say, 25c. per ton acid produced amounts to a large sum annually in a relatively small plant.

After such sulphur dioxide gases are cooled another problem presents itself in contact acid manufacture—namely, purification. Here again a saving can be made by introducing an electric precipitator, obtaining practically perfect removal of all suspended acid mist or other suspended impurities, thereby increasing the life of the catalyst, or at least eliminating the necessity for frequent replacement of expensive filter media or the inclusion of large and expensive filter boxes or towers. In actual commercial operation, over 99.5 per cent removal of such suspended matter has been obtained continuously, using electrical precipitation.

ADAPTATION OF PROCESS TO COMBUSTIBLE GAS CLEANING

Considerable development has been necessary to adapt these processes to combustible gas cleaning, but a

FIG. 3. ELECTRICAL PRECIPITATOR FOR RECOVERING TIN FUMES FROM REVERBERATORY, CALCINING AND BLAST FURNACES HANDLING TIN ORES

marked degree of success has followed these efforts. Here also the waste eliminated is primarily a labor waste, both in operation and maintenance, as well as a power waste. The dry hot cleaning of iron blast-furnace gases presented several features important from a waste standpoint—labor saving in operation and maintenance, water waste and stream pollution, fuel and power saving and, during the war, potash

FIG. 4. ELECTRICAL PRECIPITATOR FOR RECOVERING SULPHURIC ACID MIST FROM EXIT GASES FROM A 50-60-TON O. V. CONCENTRATOR

recovery. Two installations built in the United States indicate the possibilities in this field and have shown at the respective plants considerable labor saving on hot stove maintenance, together with appreciably higher stove temperatures. It has been shown by actual statistics that the blast furnaces of the United States could easily produce an amount of potash sufficient for all usual peace-time purposes. It is not the purpose of this paper, however, to discuss the potash situation, which is a complex one. Factors such as transportation rates, availability, first importance of related operations of an especially severe nature, etc., must be carefully studied to determine the final safe economic procedure. Suffice it to state that some potash can be and is being readily obtained in this way and that the isolation of blast-furnace potash by electrical precipitation could be utilized in an emergency. Potash from cement kilns was produced in large quantity during the war, and several large cement plants were operated primarily for their potash recovery with the cement as a byproduct. Rotary kiln treatment of various potash-bearing shales and slates, with electrical precipitation of the volatilized fumes, has also been shown to be feasible and a means of obtaining an economical production of potash. Should imported potash remain at a low figure indefinitely the work done on potash recovery has not been lost, having served a valuable purpose during the war and demonstrated the practicability of "concentration by volatilization," which finds uses in metallurgical and other fields.

ANOTHER FIELD FOR ELECTRICAL PRECIPITATION

The removal of dust and tar from gases of distillation of coal or from producers has offered another large field for electrical precipitation. Fuel and labor saving can be effected thereby, depending on a wide range of operation of such equipment. By temperature control fractional condensation may be obtained, saving certain redistillation operations, securing better grade byproducts, etc.

Examples could be given ad infinitum of possibilities and of accomplishment through the introduction of the Cottrell processes into industry, but the intent of this review is to give a perspective of the extent of the problems encountered, and the trend of thought and

effort directing the development of such processes as a useful instrument in the control of industrial waste. It has been shown in the investigations of various "smelter smoke" commissions, mainly the Selby Commission and the Salt Lake Commission, that if noxious gases are first cleaned to remove their suspended matter and then discharged at a high elevation and at an appreciable temperature above atmosphere, such gases will be dissipated more readily than uncleaned gases and will not do appreciable damage to vegetation. Here again the Cottrell process plays an important part, cleaning the gases without appreciable interference with natural stack draft.

Development of engineering design for electrical precipitation, with or without previous research work, must follow the trend of general industrial progress, and to the end that duplication of effort be avoided and the greatest progress made, there is quite close co-operation and collaboration among all those interested in its development throughout the world. Standardization of design for specific applications tends toward simplification of equipment requirement. Design has therefore largely followed practical commercial results, and has been almost purely empiric, but rational methods must obviously follow, indicating what limitations may be expected in miscellaneous additional applications that may be presented.

SOME FIGURES AS TO COST

Owing to the wide range of application and size of Cottrell installations, it is well-nigh impossible to give any individual set of figures on the investment necessary or the cleaning cost. The following figures, however, will serve to show what may be expected. They are compiled from plants actually built and operated during the past five years:

Complete installation investment per cu. ft. treated per minute (at temperature of treatment)	\$0.30 to \$3.75
Capacity of installations, cu. ft. per minute	200 to 3,000,000
Power consumption, kw.-hr. per 100,000 cu. ft. per hr.	1 to 2
Labor cost per 100,000 cu. ft. cleaned per hr.	\$0.007 to \$0.02
Space occupied by precipitator per 100,000 cu. ft. per hr. cleaned	500 to 1,000 cu. ft.
Precipitation efficiency obtained in commercial plants	90 to 99 + per cent

The table on page 432 illustrates the actual capacities of individual installations.

FIG. 5. VIEW WITH "POWER OFF" OF PRECIPITATOR FOR REMOVING SULPHURIC ACID MIST FROM EXIT GASES FROM O. V. CONCENTRATOR

CAPACITIES OF INDIVIDUAL COTTRELL PROCESS INSTALLATIONS

	Metallurgical Dust and Fume (Large Installation)	Metallurgical Fume	H ₂ SO ₄ and Precious Metals	H ₂ SO ₄ Mist	Precious Metal Fume and Dust	Metallurgical Fume and Dust	Air Cleaning (Gold Dust)	Metallurgical Dust	Metallurgical Dust	Pyrite Burner Dust	Producer Gas (Tar)
Investment per cu.ft. gas treated.....	\$0.50	\$2.38	\$3.75	\$3.75	\$2.85	\$2.50	\$0.95	\$1.50	\$0.67	\$3.75	\$3.00
Cleaning cost per 100,000 cu.ft. gas treated per hr.....	\$0.03	.13	.22	.25	.23	.175	.08	.08	.03	.155	.15
Temperature of gases treated.....	250- 300°F.	600- 700°F.	150°F.	200°F.	650°F.	600- 700°F.	70°F.	400- 500°F.	300- 400°F.	900- 1,000°F.	70°F.
Power consumption, kw.-hr. per 100,000 cu.ft. gas treated per hr.....	0.3	1.6	2.8	2.0	2.4	2.0	1.0	1.0	0.2	0.1	1.25
Cleaning costs per 100,000 cu.ft. gas treated at 70 deg. F.....	\$0.05	\$0.26	\$0.25	\$0.30	\$0.48	\$0.35	\$0.08	\$0.14	\$0.04	\$0.50	\$0.15
Weight of gas treated in tons per hour, approximately.....	4,000	50	26	8.4	8.0	14.4	53	66	270	18	5
Efficiency of removal of suspended matter	85-90%	98+%	99+%	99+%	99+%	97+%	95+%	95%	91%	99%	99%
Weight of precipitate in lb. (av.), per 100, 000 cu.ft., approx.....	6	16	5-15	125	3	8-10	1.0	40-50		7.5	15

NOTE.—Gas volumes taken at temperature of treatment, except where otherwise specified.

The foregoing outline indicates in general what has been done in the past few years, and can be done to an even greater extent in the future, toward the curtailment of industrial waste in the field of gas cleaning (for use in various operations) or for the prevention of atmospheric pollution. Close attention to all of the various factors entering into the solution of these problems is essential to ultimate success both technical and

FIG. 6. VIEW WITH "POWER ON" ILLUSTRATING THE EFFECTIVENESS OF ELECTRICAL PRECIPITATOR FOR REMOVING SULPHURIC ACID MIST FROM EXIT GASES FROM O. V. CONCENTRATOR

economic. By conservative consideration of these problems as they arise much good may be accomplished, reacting favorably on the industry affected, creating new processes, making certain commodities more readily available, or assisting in the general betterment of public health and property to the end that the needs of our modern civilization may be cared for and even anticipated without appreciable detriment to anyone—the industries, the workers, or the public. Progress in this direction will therefore be slow, but if properly directed should be continuous.

Waste and Inefficiency in the Industries

A Series of Short Articles by Industrial Leaders Featuring the Outstanding Causes of Waste in More Than a Score of Industries—Frank Confessions of Inefficiency Due to a Wide Variety of Causes

EDITOR'S NOTE: It is not often that technical executives will speak frankly regarding the weak spots of their industries. They may recognize them clearly and work assiduously to eradicate them, but they are apt to prefer not to talk about them, at least for publication. Accordingly the series of short articles presented herewith assumes a degree of importance that is not likely to be overestimated. Men fully familiar with the industries whereof they speak and fully cognizant of the necessity for eliminating waste and inefficiency have frankly laid bare the conspicuous weak spots. The reader will be struck by the variety of causes assigned by different writers. Lack of statistics, rule-of-thumb operation, lack of team work, lack of technical men and their engineering knowledge, poor management in high places—these are a few of the causes assigned.

A careful reading of the entire series will prove valuable to every chemical engineer regardless of the industry in which he is engaged. He has before him, in effect, brief reports of competent investigating committees whose findings may be accepted at their face value because in some instances they are the butt of their own criticisms.

The Wastes Caused by Carelessness

BY PHILIP DEWOLF
Davison Chemical Co.

If a job is done exactly right, which, of course, means that there are no mishaps of any kind, the result will be 100 per cent of the possible. That does not mean a 100 per cent yield in any chemical process, because chemical reactions go only to equilibrium anyway; also the last few per cent may cost more than they are worth, so cannot be considered within the limits of commercial possibility.

But the greatest enemy of the proper yield is lack of thoroughness. We all make mistakes; we all forget, and the only way to get the yield the greatest number of times is to cultivate the habit of thoroughness. It can't be taught—it must be learned.

CONSPICUOUS WASTES DUE TO LACK OF THOROUGHNESS

Let me give a few examples of troubles from this cause that have come within my experience.

During the war at a munitions plant oil-of-vitriol lines were put into service with bewildering rapidity, and each one started off and ran well until the very last one. And when the pumps were started in it every member of the crew was burned—not a wrench had been put on the flange bolts of the acid lines in the absorber house—someone had not been thorough.

A copper smelter was built 11,600 ft. above the sea, in the mountains of Peru. It was designed by an engineer who had built six large and successful smelters,

and, while of moderate size, was supposed to be the last word. The river furnished just sufficient power to operate the machinery provided. When the metallurgist started to figure his charges he couldn't get them to come out right—the designer had forgotten that at 11,600 ft. the barometer stands at 19 and 50 per cent more air, by volume, is necessary. That meant a new power plant further down stream—pretty costly lack of thoroughness.

This same smelter, owned by one of the largest and most successful copper companies in the world, was fed by many small mines, and before the last power house was finished a flaw in a group of titles was found, and the company abandoned its \$2,000,000 investment—a high price to pay for a careless lawyer.

One of the big munitions plants decided to use marl for neutralizing its wash water before releasing it to the river. One large body of marl was available, soft enough to be a steam-shovel proposition, but it had the drawback of roundabout transportation. So another "marl" deposit was found and bought. It was in rock form, so an expensive crushing and distributing system was installed at the plant. The first few hopper-bottomed cars arrived; the pieces of rock were so large they would not discharge through the hoppers and had to be unloaded by a crane, and were so hard that every crusher tried was broken. So without getting one pound of "marl" into the river this \$150,000 plant was abandoned because the engineer had satisfied himself as to transportation and chemical composition, but had paid no attention to physical condition nor to crushing facilities at the quarry.

THOROUGHNESS PAYS IN THE CHEMICAL PLANT

One very much used war chemical was bought by the Government at 50c. a lb. One of the large manufacturers made it at 19c. a lb., but some smaller contractors, without the technical skill available to the larger one, could not make it for 50c. So a "flying squadron" of good men was organized by the big maker, and was sent around to the smaller plants to cut costs and help production. In almost every case the trouble was found to be insufficient washing, and in every case costs were cut well inside the 50c.

At the 15,000-hp. boiler plant of one of our big chemical companies steam costs 26c. a thousand pounds, while at the best of the boiler plants of a still larger company it is 90c. To be sure, the larger company has no very large individual plants, but neither does it begin to pay the same attention to water softening, proper combustion of fuel, or other smaller but in the aggregate by no means unimportant items. The first company's thoroughness pays.

Examples could be given almost without end, but they would all point to the same thing—viz., how much it costs not to be thorough.

Baltimore, Ohio.

Dye Industry Lacks Business Knowledge

BY "INSIDER"

The manufacture of coal-tar intermediates and dyes is just like any other business, and suffers from the same business diseases. The great variety of products, coupled with an uncommon complexity of manufacturing practice, complicates the symptoms and intensifies ordinary business troubles to a degree not met in the usual industry. This is, however, merely an intensification, and nothing new or mysterious.

"WE DON'T KNOW OUR BUSINESS"

The principal cause of waste in the dye industry today is lack of knowledge of the business by those engaged in it! Horrible confession, we don't know our business, but it's true! This lack of knowledge is monopolized by no one group, but is common to all.

Beginning with the financier, we find a startling lack of appreciation of the risks of the business to which he pledges his resources and the normal ways of minimizing them. Common gambling would represent a true definition of his activities in most cases. Next, of red tape artists suppliant before a mysterious scientist we have had plenty, but the understanding organizer is still absent. Chemists of good training are ever present, but their dyestuff experience is attested by the prevalent low yield figures. Lack of plant discipline is indicated by a watch at our plant sewers—it's an even chance that the operating man either lets the batch by, or finds it desirable to dump it. As for the dyestuff engineer, he is still a dream. Witness our hodgepodge plant equipment and the primary failure to utilize expensive manufacturing equipment and buildings for manufacture rather than for storage. Again, where is the counterpart of the time study of the metal industry?

This view may be called extreme, but space does not permit amplification. One ever-present fact is very indicative—in no branch of the business can a full answer be given to a question without an extensive investigation, not only into the subject matter of the question itself but also into the underlying fundamentals. Commonplace knowledge of the latter is unavailable to most in this business; how then can we be said to know it?

In the past, circumstances have been largely to blame for this lack of knowledge, but we ourselves will be entirely at fault if we fail to correct it in the near future. Some companies have made a considerable advance already, but it is believed the picture here given is true of the average organization.

FINANCIAL, EXECUTIVE AND TECHNICAL PERSONNEL NEEDED

Assuming that we obtain from the public an indication of probable continued support, we must attract to the industry broad-gaged financial men to head our companies, who are willing to lay out a long-time manufacturing program and who are able to back it, even if it means waiting several years for returns. These men must further attract broad-gaged executives who are willing to learn the business and who realize that it takes time and money to build up an art. Chemical engineering, operating and commercial research must be undertaken in a systematic manner, and if the industry is to progress, this research must be undertaken by permanent employees of the companies involved. Letting the other fellow experiment, and if

he goes bankrupt, buying his results at a discount; or, if he succeeds, stealing his men, must cease. Freer interchange of general technical information between companies is an important desideratum. The perfection of organization and methods compelling the quick seizure and immediate utilization of the results of this research is essential. A policy of encouraging and assisting in the development of subsidiary industries, such as chemical machinery manufacture, should be practiced. Finally, we must welcome any methods which will tend to rob the industry of its mystery and thereby render available to it the recognized standard practices of other industries.

Thus can we be sure that we have learned our business, and thus only can we rid ourselves of the charlatan, the mysterious alchemist, the get-rich-quick schemer, the possessor of fake processes and the bribe-giving salesman. And when we have learned our business we will not be afraid to think of next year, and spend perfectly good money *now* preparing for it.

The Rubber Industry Learns Its Lesson

BY ANDREW H. KING

When the topic of waste is first mentioned, one usually thinks of some small insignificant dribble which if allowed to continue will eventually consume a large share of the profits. There is, of course, this type of waste in the rubber industry. However, through the work of alert salvage departments this loss is kept at a minimum.

But unfortunately there is such a thing as "saving at the spigot and wasting at the bung." For waste exists in high places as well as in the low. It is of waste in the high places that I wish to call your attention.

DISREGARDS THE WARNINGS OF THE ECONOMIST AND STATISTICIAN

In common with several other industries, rubber is now recovering from a very serious attack of indigestion, which in the business world is known as overproduction or overexpansion. Losses have reached almost incredible heights. A number of firms have gone into receivers' hands, while others have been forced to undertake plans of reorganization, which in one or two instances could hardly have been more rigorous.

As mentioned in the beginning, the writer feels that the severity and extent of the disaster were largely due to waste in high places. The first and probably the most unpardonable sin was the almost wholesale disregard of the opinions of the economists and statisticians. For at least a year before the "flood" one prominent financial intelligence organization was crying: "*Beware, the end is at hand.*" Few listened, but the majority kept right on with their overproduction and overexpansion as if nothing could ever happen that would puncture their soap bubble of prosperity. They were drunk with their own success.

WANTON SPENDING WITH NO EYE TO THE FUTURE

The second mistake was that very few firms laid by a rainy day fund. And such that did found their estimates wholly inadequate. Perhaps they thought it would never rain. Throughout the period of prosperity there was very poor control of spending. Purchases of all kinds, contracts for future delivery, new build-

ings, new machinery and new equipment were authorized with almost no check as to their need. The executives who should have been on the job were asleep.

Not only was there no respect for statistics as to general business conditions but there were no authentic statistics relative to their own business. Years ago a writer estimated that the average car consumed five new tires per year. This figure misled many who should have known better from their own experience if from nothing else. The estimate above mentioned was made when all tires were "fabrics." Today they are nearly all "cords" and the mileage has been multiplied by at least two and in many cases three or more.

Then again the art of repairing tires has made wonderful progress within the past few years. Today an accident to a tire no more spells its funeral than an accident to a car. New parts are placed in each.

The severe retrenchment which followed has brought once more a healthy condition to the rubber industry. It is hoped that the lessons have been well learned.

New York City.

Technically Trained Men, the Need of the Food-Preservation Industries

BY W. V. CRUESS

Assistant Professor of Fruit Products, University of California

Many companies engaged in food preservation spare no expense for up-to-date equipment and buildings. Often their sales and advertising departments are given the fullest support. Yet these same companies all too frequently intrust the management of production to men who have had no scientific training and who in many cases are opposed to the application of science in the plants under their control. In other cases a small amount of money is appropriated for a laboratory and for a chemist who is expected to return several thousand per cent on the investment at once; or the chemist becomes merely an unimportant adjunct to the advertising department. Both of these viewpoints are wrong.

CHEMISTS AND BACTERIOLOGISTS FOR THE CANNING INDUSTRY

The food-preservation industries are above all else badly in need of scientifically trained and experienced plant managers. Of almost equal importance is the need of well-equipped laboratories manned by high-class research and control chemists and bacteriologists. The National Canners Association has been of immense value to the canning industry. The value of the research work and control measures accomplished by Dr. W. D. Bigelow and his associates cannot be overestimated. Yet in the canning industry itself we have need for hundreds of university-trained men in production, research and control, if the canning industry is to come into its own.

The need is even greater in the pickling, beverage and fruit drying industries. That investment in scientific training and skill pays has been amply proved by such organizations as the H. J. Heinz Co., the Campbell Co. of Campbell's soup fame, the Van Camp Co. and others that could be mentioned.

MUST START AT THE BOTTOM

The food-preservation industries are not entirely to blame for the present condition. Too few of our university graduates are willing to enter the plants at the "bottom of the ladder." It will be necessary in many

cases for them to don a pair of overalls, learn present factory methods and strive for the superintendency or management of the plants. Observation has shown that such men usually advance rapidly. Once this pioneer work of establishing technically trained men in industry has been done, research and plant control will come quickly and naturally, to the great benefit and advancement of the industries concerned.

Berkeley, Cal.

Industrial Waste of Food Products

BY G. A. MENGE

Libby, McNeill & Libby

Considering industrial waste from the standpoint of failure to conserve and utilize byproducts to the best advantage, the food industry in general is perhaps less deliberately guilty than some other industries, considering that it is still largely based upon rule-of-thumb methods. Perhaps the broadest opportunity in the food field for waste of this kind exists in the great meat-packing industry, but whatever just indictments may be found against that industry it is a well-known and very generally recognized fact that indifference to industrial waste is not one of them.

IMPORTANT FOOD PRODUCTS WASTED

In other branches of the food industry, however, the total aggregate waste resulting from failure to conserve and utilize most efficiently such valuable material as skim milk and buttermilk in the operation of creameries, whey in the operation of cheese factories, sound culls and other discarded material of like nature in the food-canning industry in general and in the fruit industry in particular would undoubtedly reach staggering proportions. More or less numerous and intensive studies now in progress on some of these problems will doubtless result eventually in much greater conservation and more effective and economic utilization of such waste materials than is true today.

If, however, we apply to our text sufficiently comprehensive interpretation to include waste or losses resulting from avoidable spoilage of manufactured food products, the food industry becomes involved in a tremendously serious indictment.

WASTES THROUGH MISMANAGEMENT

If my experience in the food industry is typical and my observations accurate, waste through preventable spoilage in this industry is often directly traceable to inefficient management in one or more or all of the major functions of the industry, from central administration to selling, including manufacture and distribution as well as all functions incidental to these. Lax and inefficient management at any major point in the industrial path, especially in central administration—the hub of the industrial wheel—is almost inevitably reflected, generally in aggravated form, at all other points. Conversely, a high degree of efficiency in any one major function, especially in central administration, will surely induce favorable reaction all along the line. Obviously the scientific development of a strong organization, with sharply defined and closely co-ordinated functions, adequately controlled and checked and under the responsible leadership of thoroughly qualified men, is the remedy for waste through mismanagement.

Perhaps the largest proportion of preventable waste through spoilage in the food industry is due to rule-

of-thumb or unscientific methods of manufacture. To the extent that this is true such waste, in my judgment, can be very largely prevented by drawing more generally and more intelligently upon thoroughly qualified technical and scientific service, with capable, efficient and responsible representation in the administrative organization. It is my firm conviction, the opinion of most so-called practical men to the contrary notwithstanding, that the personnel of every food-manufacturing plant should include a man of such thorough technical training, in scope and degree, as to qualify him to recognize the sources of danger, often very subtle and insidious, to prescribe and apply proper and adequate protection when possible and to give competent scientific advice and help in the various technical phases of plant operation with respect to the food product involved. Such service in such degree, in my judgment, expresses the principle of proper scientific control in the food industry in its simplest terms. Elaboration of it may be indicated with great advantage in specific cases.

Disastrous experiences of an economic nature now and then in the food industry have gradually forced some degree of application, as well as recognition of the value, of scientific methods and control as a means of insuring safety, improving quality and greatly reducing waste of manufactured food products, but we still have a long road to travel before this development is complete.

Causes of Waste in the Textile Industry

BY ONE WHO KNOWS

One of the most apparent reasons for the waste that occurs in the textile-manufacturing industry is the status of intermittent operations which obtain in practically all divisions of this trade. In the majority of plants this spasmodic activity is caused by seasonal conditions which make for an abnormal rush during certain periods and equally abnormal idleness at others. The result is that manufacturers are not able for the most part to figure on 100 per cent capacity in calculating their costs, but must take into consideration the overhead of idleness.

This condition leads naturally to more or less discontent on the part of operatives, who cannot be assured of year-around employment, with the consequence that labor turnover is thereby increased and cost enhanced. To this may be added the liability of labor difficulties, which are more or less recurrent in the textile industry and which frequently last for a protracted period.

It is also apparent in the textile trade that there is a lack of planning ahead in the various operations of the mill. This produces a certain amount of idle machinery that could be utilized to advantage if plans were made to provide a continuous process from one step to the next. This lack of foresight also increases overhead.

BETTER COST METHODS, TECHNICAL RESEARCH AND ECONOMIC DISTRIBUTION NEEDED

It must be admitted that the textile industry shows no general inclination to adopt up-to-date or standardized cost methods. Naturally there are exceptions to this statement, but those manufacturers who are content with methods long discarded are sufficiently numer-

ous to characterize the industry as being decidedly backward in this respect. The effect of this apathy is far-reaching and accounts in a measure at least for much of the speculation and wide range of prices which is frequently noted in the selling markets. Another feature that is not complimentary to this industry is the small amount of technical research work that has been done in the past, though it must be admitted that more attention is being paid to this subject, and the hope for increased efficiency through better technical knowledge of materials and processes is widely entertained.

The uneconomic methods of distribution might be touched upon, though this is going somewhat afield in a strict discussion of waste in the manufacturing industry that goes no further than the production of the fabric. The passage of manufactured product through many hands means an accumulation of profits for each handler and an enhancement of cost which is an economic waste to the ultimate consumer. Here also, however, the tendency is apparent of a more direct contact between the manufacturer and the consumer of his product.

Inefficiency in the Leather Industry

BY JOHN ARTHUR WILSON

Chief Chemist, A. F. Gallun & Sons Co.

The most conspicuous cause of inefficiency in the leather industry is ignorance of the basic principles of tanning. As many as fifty distinct operations may be employed in converting the raw material into finished leather, when perhaps less than half of the enormous amount of labor and materials involved would yield a better leather, if only the relation of each operation to the entire process were sufficiently understood.

UNNECESSARY INCREASE IN TANNING OPERATIONS

Present methods of leather manufacture are largely the result of centuries of hit-or-miss juggling. By chance someone would discover that the introduction of a new operation caused an improvement in the final leather, but little realizing that the new operation merely counteracted the bad effects of some other operation that was either unnecessary or improperly conducted. It is like using alkali at one stage and an equivalent amount of acid at another when a neutral solution is desirable at all stages. Eliminating acid or alkali alone would cause trouble, whereas time, labor, materials and an improved product would be gained by eliminating both acid and alkali. The new operation might cause an improvement in some respects and introduce difficulties in others, requiring the introduction of still further operations for correction. Thus the tendency has always been to increase rather than decrease the total number of operations, and chiefly through ignorance.

ADDING SOLUBLE MATTER AND THEN REMOVING IT

A glaring example of this sort of thing is found in a certain manufacture of heavily greased leather where a tanner treats the hides in the final stages of tanning with very concentrated liquors to get an increase in weight. The large amount of soluble matter now present prevents the greases from penetrating the leather. His method of overcoming this difficulty is then to remove the excess of soluble matter by a scouring operation instead of ceasing the practice of loading the leather with concentrated liquors. He does not appre-

ciate the fact that the concentrated liquors caused the trouble nor that the scouring operation corrects it by removing the excess of soluble matter.

MUST RECOGNIZE VALUE OF CHEMICAL TECHNOLOGY

Incorrect beam-house methods necessitate corrective operations in or prior to tanning, just as crude systems of tanning increase the number of operations required in connection with fat-liquoring, stuffing and coloring. Often costly materials are wasted because their functions are imperfectly understood or because it is not known how to strengthen a used liquor so as to give it the properties of a fresh one.

The ultimate cure for this state of affairs lies in an intensive study of the nature of the interactions between and the physical and chemical properties of proteins, enzymes, tannins, emulsions, dyestuffs and electrolytes, followed by an intelligent application to tannery processes. Unfortunately the industry as a whole has not yet awakened to the value of such study and apparently still doubts that an increased knowledge of chemistry will result in any great increase in the efficiency of the tannery. Some will probably sleep until it is too late to meet competition.

Meat-Packing Industry Contributes Too Much to Fertilizer

BY L. M. TOLMAN

Chief Chemist, Wilson & Co.

The meat-packing industry has been noted for its attempt to utilize in some way every byproduct of the animal, and to a very great extent this has been done especially by the larger companies. It has, however, been realized for some time that a great deal of the material going into fertilizer could be utilized in some more valuable form—particularly is this true of the nitrogenous waste. At the present time it might be said that the most outstanding waste in this industry, if it may so be termed, is the material which goes into fertilizer. This material if it had been handled in the proper way might be made into either food products or into certain technical products, such as gelatine and glue.

BETTER UTILIZATION OF BLOOD

An example of the proper utilization of nitrogenous material could be well illustrated in the handling of blood. Blood consists of serum and red blood corpuscles, which can be separated to produce, in the case of the serum, a product known as blood albumen, which is of great value as a water insoluble glue and finds important uses in the textile industries. The red blood corpuscles consist largely of hemoglobin, which has been found to be of value in medicine. So it is that two valuable products can be made from a material which was formerly used almost entirely as dried blood for fertilizer. Moreover, it is undoubtedly a waste not to use blood for human food.

FAULTY HANDLING DEGRADES VALUABLE MATERIALS

Tankage should be considered similarly. Here we have a material carrying from 40 to 60 per cent protein. At one stage in its handling it was largely an edible product (except where it came from animals which were condemned on account of disease), and it was only the faulty handling that has degraded tankage into an inedible fertilizer substance.

In a general way it might be said that the greatest waste now apparent in the packing industry is that

which is brought about by spoilage or so degrading high-grade edible or technical materials until they are only useful as fertilizer.

Recent developments in the field of medicine have indicated that many valuable medicinal substances can be prepared from the glands and organs. Undoubtedly the developments of the future will be along the lines of utilization of all of these substances and their manufacture into the very highest grade of pharmaceutical preparations.

Waste in the Glass Industry

BY E. WARD TILLOTSON, JR.

Assistant Director, Mellon Institute of Industrial Research

Some years ago a writer aroused the indignation of glass manufacturers by stating that, despite much excellent management and notwithstanding the use of many ingenious machines, the main policy of the glass executive was to be described by the slogan, "Save at the spigot and waste at the bung." This expression, derived from a defunct industry, may divert the attention of the present reader from the main theme of this contribution and to some, in fact, the analogy may be quite unintelligible. The thought to be conveyed was that the manufacturer failed to recognize the necessity for obtaining certain essential information the lack of which often resulted in the loss of production for a considerable period of time or at least in the manufacture of an inferior product. The loss of a tank of glass due to the use of materials the unsuitability of which would have been indicated by chemical analysis was a case in point.

GLASS MANUFACTURER REQUIRES FACTS

The same thought has been expressed recently to the writer by a prominent and successful glass manufacturer, who, speaking of the industry at large, says:

We neglect facts; we reach decisions and take action without the readily available facts which bear on the matter in question or else we do nothing because the facts which would stimulate to action are not at hand. This is true not only of such information as physics or chemistry or mathematics can supply, but also of the facts which a study of simple records would reveal in the individual plant.

WASTES DUE TO MANAGEMENT AND OPERATION

Waste in the glass industry is of two sorts: The first type of waste results from the lack of proper management and is represented by poorly planned factories, inadequately constructed buildings which provide unpleasant and in some cases unhealthful working conditions, carelessness on the part of the workman, the improper selection of raw materials and the lack of standards for them, and the use of cheap labor for important operations such as the care of the gas producers and the regulation of the furnaces. As an instance, the owner of a small factory states that the systematic reading of gas meters and the constant checking of the proportions of gas and air entering the furnaces have resulted in a daily saving of 150,000 cu.ft. of gas.

WASTES DUE TO MATERIALS

The second kind of waste is due to fundamental limitations of materials, particularly of the refractories, which necessarily are employed. No really satisfactory substance is available for manufacturing those parts of the furnace which come in contact with

the melting glass or for the "crown" and other parts of the furnace. The refractories not only are dissolved slowly by the molten glass but also have a softening temperature only slightly above that of the furnace. Indeed, if the whole mass of the refractory block were to be heated uniformly to the temperature of the furnace, it would soften sufficiently to allow the structure to collapse. Consequently it is impossible to conserve fuel by insulating the furnace; but, on the other hand, it is necessary to increase the radiation (which amounts to around 40 per cent of the total fuel) by cooling the exterior by artificial means. Much of the product which is rejected, the "shrinkage," is discarded because of faults which may be traced back, either directly or indirectly, to the construction or operation of the furnace. Excessive loss of product also is caused, at times, by an occasional use of unsuitable batch materials and by a lack of control of the temperature in the leer.

TO PLACE THE GLASS INDUSTRY ON A SCIENTIFIC BASIS

The glass industry, certain branches of which owe their present status to engineering, will eventually meet its problems in waste through the infusion throughout the industry of the principles of science, not only in the way of research and control from the standpoints of chemistry and physics but also in considering questions of hygiene (including the prevention of contagion, poisoning and injuries) and in placing the several operations and, in fact, the entire organization on a scientific basis. That the more successful glass manufacturers maintain intensive investigations of these and other problems is significant.

Pittsburgh, Pa.

Improvements to Be Realized in the Cane Sugar Industry

BY C. E. COATES

Dean Audubon Sugar School, Louisiana State University

The manufacture of sugar from sugar cane when carried out properly in the most modern plants is exceptionally free from waste. The cane is weighed, the juice is weighed, the resulting sugar and molasses are weighed, and there is a loss unaccounted for of only a fraction of 1 per cent. From a mechanical standpoint, the steam pipes are insulated, the furnaces are provided with suitable gages and there is a heat recovery considerably above the average. The engine work is good, mills are efficiently run, the evaporation is carried on in triple and quadruple effects, graining is done in insulated pans and every effort is made to conserve heat by economizers and the like. Where any of these twentieth century devices are lacking or inadequately provided for, loss in both sugar and in heat is bound to occur.

On the whole, the greatest waste is in the mechanical end, because the economy of high-grade and therefore expensive mechanical engineers is not thoroughly appreciated. The chemist, on the other hand, is generally considered indispensable, and waste from inversion or from molasses of too high purity is not usual. The bacteriologist, however, is just beginning to be appreciated and considerable avoidable loss occurs from lack of consideration of his possible services. Fermentation frequently does more damage to the sugar house itself than is ordinarily known and finished raw sugars lose

materially in transit, because of inversion due to a number of different avoidable fermentations.

NEED OF BETTER UTILIZATION OF BAGASSE AND MOLASSES

Perhaps the greatest waste occurs in the utilization of the byproducts, which are bagasse from the fresh cane and molasses.

Bagasse is ordinarily burned. As a fuel a ton is worth about one-fourth as much as a ton of coal. It would have a considerably higher value if made into building board or paper stock. It is also possible to separate it chiefly into pith and fiber and from the pith plastics could readily be made. The economies have been effected only in isolated instances. Molasses can be fermented into industrial alcohol, and from this motor spirit can be made. This industry is at present quite promising. Molasses may also be used as a cattle feed, and this is done to a large extent. There seems to be no reason, however, why final cane molasses can not be made of such a quality that it would be also fit for human consumption. Comparatively little attention is paid anywhere to quality at this point.

The real waste in the cane sugar industry, and it is a waste of great magnitude, lies in the fact that much cane sugar is made by a rule-of-thumb method, with little consideration given to the teachings of applied science.

Baton Rouge, La.

Basic Technical Information Needed by the Edible Oil Industry

BY JOHN C. INGRAM

Development Engineer, Morris & Co.

An article dealing with the elimination or minimizing of waste in any industry is essentially a dissertation on the basic problems of that industry, and these are naturally receiving some attention from all those actively engaged in the industry. In the edible oil industry the precipitous decline of prices without any possibility of a corresponding decline in costs has brought about so-called economies which have tended to interrupt somewhat the progress being made in the solution of its fundamental problems. Work on the accumulation of basic technical information seems to have been indefinitely postponed and only those problems which promise immediate financial reward are being given any considerable attention.

From a host of pressing problems the following may be selected as typifying the trend of the present-day effort toward the elimination of waste in the several principal processes of this industry.

PROBLEMS OF CRUSHING

About 85 per cent of the edible oils of the country are produced primarily by the cottonseed crushers, who are confronted with the difficult problem of reducing the idle time of their numerous plants. The operating time of cotton-oil mills varies with their location and with the seasons, approaching six months as a maximum, while some have been known to operate but six weeks out of a year. The widespread distribution of oil mills throughout the cotton belt enables the producers to handle between 60 and 75 per cent of the total production of seed, but the capital outlay required is non-productive for the greater part of each year.

The reduction of overhead charges by increasing the

operating time of plants is the most pressing problem before the crushers today, and a number of solutions have been offered. A brief outline of several of these solutions together with a few comments are given below.

REDUCTION IN NUMBER OF MILLS AND STORAGE OF SEED

There can be noticed at present a tendency toward fewer mills of larger capacity, centrally located. The perfection of methods for the drying of cotton seed and the provision of adequate storage facilities promise some relief from the handicap of seasonal production. Part of the saving in freight on dried seed would be used to increase the mill's profitable working radius and the remainder to defray the expenses of drying and storage. Preliminary surveys indicate that the saving thus effected is distinctly worth while.

SUPPLY OF RAW MATERIALS OTHER THAN COTTON SEED

During the era of high prices an appreciable quantity of peanuts and soya beans were handled profitably by the mills, but under present conditions it is doubtful whether the working of these materials contributes much toward the solution of the dormant season problem.

The development of an adequate supply of foreign oil seeds and nuts gives promise of furnishing some relief to those mills which are favorably located. For some time certain importers have been offering small lots of these materials for experimental work with the view of developing these projects should the results prove favorable. It is well recognized by the leaders in the edible oil industry that the most likely source of supply is toward the south—in Mexico, Central and South America—and the materials which look most promising at the present time are sesame seed, cohune nuts and palm kernels.

LOSS IN SOAPSTOCK AND IN FULLERS EARTH

Like the proverbial cat, our old problem—the oil retention of soapstock—has returned with the era of comparatively low-priced oil, the war solution being no longer attractive when all cost factors are considered. This foots, or soapstock, selling around 1½c. per lb. still contains 20 to 26 per cent of 6 to 7c. oil. The refining process is in crying need of considerable study from the standpoint of colloidal chemistry.

Approximately 25,000 tons of fullers earth is used each year by the edible oil industry. The spent earth contains anywhere from 15 to 40 per cent of retained oil, depending on the type of earth. Some efforts are being made to recover the oil and some organizations are attempting to re-use the earth, but as yet no process has proved of sufficient financial interest to be universally adopted, and this material is still a liability.

EFFICIENT DEODORIZATION

This process, developed through decades of cut-and-try experimentation, is essentially the removal of odor bodies by distillation in steam. As such, the main item in its cost is steam, and attempts at cost reduction in this phase of the industry are very likely to aim at higher steam efficiency.

The main problems in deodorization are not connected with direct savings in the process, but with the elimination of waste, through the improvement in keeping qualities of finished oils.

Chicago, Ill.

Cement Industry Needs More Chemical Engineering

BY JOHN GODFREY DEAN
Chemical Engineer

The cement industry has suffered from many of the so-called industrial ills such as overcapitalization, excessive promotion, poor locations, lack of systematic cost accounting, poor management, local overproduction, unreasonable competition, poorly designed plants, lack of 'safety first' provisions, excessive power and fuel consumption, loss of dust and waste heat, etc., to the end of the chapter. Many of these disorders were general, some were more or less epidemic, and a very few were exceptional.

When we consider the rapid expansion that has taken place in this industry during the past twenty years, it is not at all surprising that it has suffered from the usual disorders of youth and inexperience.

CO-OPERATION DISPLACES SELFISH METHODS

By certain processes of elimination, foreclosure and consolidation many of the above-enumerated abuses have been overcome. During the past few years, by a process of education fostered and encouraged by the Portland Cement Association, the industry has become nationalized to a certain extent and a real spirit of co-operation has taken the place of former selfish business methods. This has resulted in a mutual exchange of ideas and experiences. The elimination of waste and inefficiency of manufacturing, marketing and business management has been discussed openly and candidly with great benefit to the industry. In particular, the educational work and propaganda carried on in the interests of "safety first" and the statistical work of the association should be mentioned as being of special service to the industry.

In spite of the many improvements that have been made in machinery and manufacturing methods there remains a great deal to be done, especially in increasing kiln production and efficiency, a better understanding of the essentials of fine grinding, elimination and collection of dust, conservation of heat, reduction of power and labor requirements, and the recovery of byproducts from the stack gases, to mention a few of the more important problems.

CEMENT PROBLEMS ARE CHEMICAL ENGINEERING PROBLEMS

It is my opinion that one of the essentials in the solution of these problems is the recognition of the fact that they are largely chemical engineering problems. In fact very few operations connected with the process of cement manufacturing are entirely mechanical or chemical, and it seems that in many instances proper consideration has not been given to the latter phase of the subject. In order to handle the large tonnage of material satisfactorily and economically the mechanical operations and equipment must necessarily be of a high order of excellence. However, since the ends attained by the various mechanical operations are so largely chemical, the chemical considerations should be of equal importance.

Many companies employ routine chemists and testers who have been recruited largely from the ranks with very little chemical training outside of what has been gained in the plant laboratories. The excellent practical experience of these men cannot be denied and on account of their more or less restricted responsibilities they have been able to meet the requirements. In order

to meet the requirements of the larger field of chemical opportunities better trained technical men are manifestly needed.

It quite often happens that a few degrees variation in the temperature of the drier atmosphere or a slight change in the physical condition of the materials or some other scarcely appreciable variation will materially affect the output and quality of the product. Again, certain methods of operation or certain types of machinery will give excellent results in one plant, while in a neighboring plant the same operations and machinery under practically the same conditions will be quite unsatisfactory.

These problems and many others of similar nature, and particularly the whole field of kiln operation, call for careful investigation and intelligent supervision by well trained chemical personnel. This, in my opinion, would hasten the solution of many of the problems peculiar to this industry and would play an important part in the elimination of waste and inefficiency.

Parma, Mich.

Wasteful Methods of the Naval-Stores Industry

BY V. R. CROSWELL

Naval Stores Division, Hercules Powder Co.

The naval-stores industry of the United States produces about 25,000,000 gal. of turpentine and 834,000,000 lb. of rosin, with an approximate value of more than \$40,000,000. About 90 per cent of this is produced from the living trees (the Southern long leaf yellow pine) by gashing the trunks and collecting in cups the oleo-resin (gum) which flows from the wound. The remaining 10 per cent is obtained from dead wood and stumps of the same tree by destructive distillation or by chipping up the wood, driving out the turpentine by use of steam and extracting the rosin by the use of a solvent.

SEVENTEEN CAUSES OF WASTE

The principal wastes in this industry may be summed up as follows:

1. Working young saplings. Government investigation has shown that the tapping of any tree less than 10 in. in diameter is a loss to the operator regardless of the market value of his products.

2. Poorly placed cups and aprons. On some workings as high as 20 per cent of the gum never reaches the cup due to improper condition or arrangement of the aprons and cups. This particular loss might conservatively be placed at 5 per cent of the gum for the whole industry.

3. Loss of volatiles through exposure of the gum. Probably more than 7 per cent of the turpentine evaporates from the gum before it is worked at the still.

4. Contamination of the gum. Dirt, bark, chips and needles falling into the cups (besides staining the gum and reducing the grade of rosin) will absorb a certain amount of this gum which is never recovered, although the foreign material is strained out at the still.

5. Loss of fresh gum through heavy rains. Fresh gum floats on water. After losing some of its volatile oils, it sinks in water. Heavy rains fill unprotected cups and occasion considerable loss in the fresh gum.

6. Improper chipping. Because of the character of their lease or their ignorance of the technical side of their work, operators often turpentine trees "to death"—a practice which materially reduces the amount of gum obtainable from the tree. Work done by the Forest Products Laboratory indicates that increased yields

might be obtained by even shorter chipping than is generally considered good practice at the present time.

7. Coloring matter from poor cups. Metallic stains from cups lower the grade of rosin produced.

8. Improper distillation. It is the rule rather than the exception to run the still and worm condensers hot, and to use uncovered receivers for the turpentine. Much loss through evaporation is the result. Careless or unintelligent handling of this operation may cause the contents of the still to foam up through the condenser and start a fire.

9. Character of containers. The container constitutes 20 per cent of the weight of a barrel of rosin, which results in excessive freight charges for producers and consumer. No better container has been devised.

10. Unstable market. The naval-stores market is particularly subject to fluctuations. This condition of affairs increases speculation, encourages working young saplings and turpentine "to death," excuses profiteering to make a "killing," encourages low wages, discourages employment of technical men.

11. Method of financing. The factor backs the producer, the producer "stakes" his men on the future. Both take heavy risks and necessarily charge heavily to protect themselves.

12. Forest fires. The Southern pine forests suffer from this calamity as do our other forests.

13. Destructive distillation. In destructive distillation no attempt has ever been made to utilize the volatile gases.

14. In the steam-distillation process the spent chips are burned for fuel, although they could be made into paper after being expensively ground up and chemically treated.

15. Only about 70 per cent of the resinous material in the wood is extracted by the present solvents. The residual resinous material is, however, dark, and special uses would have to be found for it.

16. Solvent losses in the steam-distillation process are excessive.

17. The cost of gathering stump wood is increased 20 per cent by the general practice of taking downwood off the land at one time, and later returning to gather the stumps.

Gulfport, Miss.

Production Wastes in the Ceramic Industry

BY R. H. MINTON

General Superintendent, General Ceramics Co., Plant No. 2

The principal causes of waste in the ceramic industry may be ascribed to the following sources in the order named: Fuel waste, absence of technical control, inefficient workmanship, lack of standardization, and ignorance of costs.

IMPROVE FIRING METHODS TO SAVE FUEL

The ceramic industry consumes an enormous amount of fuel in its operations, and the question of efficiency is of great economic importance. Until the war the cost of coal was so low that there was little effort made to improve the methods of firing kilns. When it is considered that heat balances made on various types of periodic kilns have shown that only 5 to 10 per cent of the fuel heating value is used in actually firing the ware, it can be realized that the mechanical means of firing are very far from theoretical efficiency.

The fuel cost is such a large item that the present high prices have stimulated efforts to develop more economical firing methods and more efficient kilns. The

principal trend is in the direction of the railroad tunnel kiln, where the ware travels through a kiln under continuous fire. Large sums of money are being expended to install and perfect this type of kiln. When successful, it has shown a fuel saving of from 25 to 60 per cent as compared with the old periodic kilns. It is still a long road to perfection, but the tendency is in the right direction.

ABSENCE OF TECHNICAL CONTROL

Many branches of the clay-working industry involve art as well as science, and it is impossible to manufacture these wares along strictly mechanical lines. On account of variations in the raw materials true scientific control is impossible. This makes it even more necessary that every available means of technical control be employed. One of the greatest sources of loss is through lack of knowledge of the raw materials used and the loose methods of uncontrolled manufacture in which too much is left to the human element. Great strides have been made in this direction within the past ten years and the future offers great possibilities along this line.

INEFFICIENT WORKMANSHIP CAN BE ELIMINATED THROUGH CO-OPERATION

Much of the higher grades of ceramic wares is partly hand made and its quality and uniformity depend almost entirely upon skilled workmen. The war played havoc with the morale of these workers and their utter lack of interest is today one of the great trials of the manufacturer. Manufacture is carried on under restriction of union shop rules which largely prevent efficient production. This is a problem of management and only better co-operation between management and labor will result in the elimination of many avoidable losses.

EVIDENT LACK OF STANDARDIZATION

The very essence of efficient manufacture is standardized production. On account of the wide prevalence of the raw materials used in the manufacture of many kinds of clay products it is comparatively easy to start a plant. This has resulted in many small units springing up everywhere. Many of these grow by a sort of accretion and the final result is anything but an engineering product. The tendency of modern plants is to adhere to good engineering designs and to accentuate mechanical equipment in every way possible in order to standardize methods at the expense of labor.

In the highest grade wares mechanical standardization is possible only to a limited extent. Here the element of art enters and plays an important part. It is this combination of art and science, together with the difficulties and uncertainties of the processes involved, that makes the industry so fascinating to all connected with it.

WIDESPREAD IGNORANCE OF COSTS

Perhaps in no other great industry is the knowledge of costs so limited. On account of the long period of time required in the production of a given unit the average cost system becomes so involved and produces such unreliable figures as to discourage its use. The lack of cost figures results in many articles being sold at a loss, while others may be out of line, prices depending largely upon competition. As compared with many other products it is really astonishing at what

low figures many ceramic wares are sold when one considers the skill required and the risks and losses involved in the ordinary course of manufacture. The advantages of the use of a uniform system of cost-accounting in the different branches of the industry is recognized and will undoubtedly result in placing the industry upon a much more stable basis commercially.

Metuchen, N. J.

Wastes and Inefficient Practices in the Petroleum Industry

BY W. A. HAMOR

Mellon Institute of Industrial Research, University of Pittsburgh

Certain wastes and inefficient procedures are observable in the great petroleum industry, particularly in the production of crude oil. It is recognized, for example, that greater supplies of petroleum can be obtained through increased recovery from our oil fields, resulting from the development and application of more effective operating methods, and especially from the elimination of wastes. There is, in fact, a many-sided movement to effect a more rational production of petroleum by scientific study, and there have been begun investigations on the determination of the capacities and characteristics of oil sands, the proportions of petroleum not recovered by present methods of production, and the laws governing the expulsion of petroleum from these sands. But little information exists on this subject, and it will be impossible to interpret data and to evaluate various production procedures until the underlying geochemical laws are better understood. Methods for stimulating production and increasing the recoveries of petroleum from strata, including the effects of vacuum pumping, the employment of compressed air or gas, and the use of water flooding, are receiving more and more research attention; and it will be contrary to experience if some of these efforts are not fruitful in the coming years. At present, geology, the real foundation of a study of production, is insufficiently applied or understood by the average producer, and consequently much of the production is accidental.

Wastes in production also result from the formation of emulsified petroleum in oil wells. Probably all emulsions in wells are formed after the oil has left the sand, and their formation often can be prevented. The broad study of methods for excluding water from oil wells, of the effect of water on production, and of related casing and tubing problems, would likewise lead to economies.

Other wastes in the domain of production engineering include losses of oil in storage, through evaporation, leakage, etc., and losses through fires at the wells and tanks.

HOW BETTER TO UTILIZE THE NOW AVAILABLE CRUDE PETROLEUM

From an economic standpoint, a better utilization of the crude petroleum now available can be accomplished by the pyrolysis of oils now used as fuel into gasoline. Less than one-half of the petroleum produced receives an ideal separation into products. Indeed, the output of gasoline may be doubled or more without increasing the production of crude petroleum.

Pyrolysis is the leading potentiality in petroleum refining, but the ideal pyrolytic or piezopyrolytic process is not a *fait accompli*. Among the common defects of the processes in use are the loss of oil as fixed or

permanent gas, low yields, the formation of undesirable impurities, and the accumulation of carbon. In this connection it is important to note that not enough work is being done in a systematic way to show how to economize in the use of gasoline when made.

Other wastes in refinery operations result from insufficiency in fractionation, chemical treatment and storage. Certainly there should be no abatement of research on the increase of the efficiency of tower stills, condensers and heat exchangers. And then a familiar problem in refining is the chemical treatment of lubricating oils in such a manner as to prevent the emulsions which result when sulphuric acid is employed, and to minimize other losses due to its use. The most economic utilization of the residues from the acid and alkali treatments remains an open field for research; it is surprising, in fact, that these have attracted so little investigational attention and that, even in well-directed plants, they usually are used for fuel. However, in time much of the acid and soda treating will be eliminated from refinery practice.

Pittsburgh, Pa.

Preventable Losses in Petroleum Refining

BY JOSEPH E. POGUE

Consulting Engineer, New York

The petroleum-refining industry represents an estimated investment of between \$1,500,000,000 and \$2,000,000,000 and in 1920 turned out upward of 20,000,000,000 gal. of products valued at close to \$3,000,000,000. The degree of efficiency attained assumes special importance in an industrial activity of this magnitude.

The petroleum-refining industry may be divided roughly into two overlapping parts: one comprising the large, complete, usually long-established plants, making a reasonably full separation of the raw material into the products in commercial demand; the other including the smaller, newer refineries, called skimming plants, that effect a very superficial extraction of values, recovering merely gasoline and kerosene, and lumping together the remaining products as fuel oil. The efficiency of the second type of plant is necessarily less than that of the first.

The preventable losses involved in the refining of petroleum are of three general types:

(a) Physical losses of material as a result of improper or incomplete installations, controllable in part by the refiner.

(b) Imperfect separation of products resulting in the recovery of more valuable components in a less valuable form, caused in part by faulty processing but in part the result of economic conditions over which the individual refiner has no control.

(c) Financial losses arising from idle equipment as a result of excessive installations, controllable in part by better planning.

ANALYSIS OF THE PREVENTABLE LOSSES

The physical losses of oil in refining, according to statistical records, total about 4 per cent of the crude run to stills. Part of this loss is inevitable, but upward of half represents gasoline vapor included in the still gases, recoverable by methods already in use for extracting gasoline from natural gas. Such methods for some time have been commercially applied in the more progressive refineries and these could be profitably extended to other plants. The fuel consumption in most

refineries is also unduly high; proper insulation, the installation of heat interchangers and other improvements would lead to a gain on this score.

The separation of crude petroleum into its maximum range of values is effected in only a few refineries. Full attainment under this head is not commercially possible under present conditions, but many plants could install with advantage fractionating towers that would enlarge their output of gasoline by recovering the portion that is normally left in admixture with the heavier products. The Bureau of Mines has estimated that the average efficiency of gasoline recovery runs from 75 to 95 per cent and that the country's output of gasoline could possibly be augmented as much as 10 per cent by greater effectiveness in distillation. The further extension and development of cracking may also be expected to enlarge the gasoline yield.

The petroleum-refining industry as a whole is carrying the burden of an excessive equipment. For several years the volume of oil run to stills has averaged close to 70 per cent of the installed capacity. Assuming a valuation of \$1,500,000,000 for the equipment directly and indirectly concerned with oil refining, the annual cost of this idle equipment, with money at 8 per cent, approximates \$36,000,000.

The proficiency of petroleum refining on the whole is not equal to the attainments of many other chemical industries. Such an outcome, however, is an inevitable result of the rapid growth of petroleum output in advance of a balanced set of demands. The discount from full efficiency is largely the result of a bountiful and cheap supply of raw material. With a stringency in raw material an ultimate eventuality, improvements in refining efficiency may confidently be expected.

Need of Technically Trained Men in Salt Manufacture

BY W. L. BADGER

Director, Evaporator Experiment Station, University of Michigan

It is difficult to point out wastes in the salt industry, because the whole industry is in a state of technical ignorance and disrepair. It is easy to see why this condition exists. Salt was so long a byproduct of the lumber industry and made with waste steam which cost nothing that the idea of applying engineering principles to its manufacture never occurred. The story is told of an engineer who went into a salt plant in Michigan not many years ago and pointed out methods by which steam could be saved. The owner's comment was: "I don't want to know how to save steam. I have too much of it. I want to know how to use more." In too many cases men who were brought up in this atmosphere are still managing salt plants.

WASTES DUE TO LACK OF TECHNICAL CONTROL

The most striking single source of waste is the lack of application of engineering principles to the utilization of heat. The grainer process still makes a very large proportion of the total output. While there are certain uses for which the type of crystal which the grainer makes is better suited, there are many cases where grainer salt is used merely because of prejudice or habit. Much of the grainer salt now made might well be replaced with vacuum salt, thereby substituting for single-effect steam economy triple-effect economy or better. In addition to this it would amaze the average engineer to see the lack of application of ordinary engi-

neering principles in many salt plants. Heat-condensed water is thrown away and boilers are fed with cold raw water. Piping systems are many times as extensive as they need be and are seldom properly covered. The application of very ordinary precautions would result in remarkable saving of heat.

Raw material is so cheap that a certain amount of waste here is entirely justified. In most plants, however, a very little care would result in the saving of many tons of salt a day which are now lost through preventable leaks. It is a question whether any system of accounting to keep track of salt entering and leaving the plant will ever be justified.

A third source of waste is the almost complete absence of labor-saving machinery. Salt is still largely handled in wooden carts, pushed by hand. Belt and package conveyors are conspicuous by their absence.

There are many other minor sources of waste which might be enumerated. The remedy for all, however, is the same—adequate technical control. Most salt plants do not need a large technical staff. One good chemical engineer who understood the handling of materials, the handling of heat, the operation of a boiler room and how to make a few simple analyses when the occasion arose would work wonders in the average salt plant.

The industry must come to recognize the need of technically trained men, or most of the smaller plants will find themselves helpless to compete with the one or two concerns that first see the light.

Ann Arbor, Mich.

Efforts to Eliminate Wastes in the Glue Industry

BY T. R. TENNANT

United Chemical & Organic Products Co.

Having recently passed through the greatest era of wastefulness the world has ever known, there is little wonder that as a nation and as individuals we are experiencing a reluctance to coming back to a normal and sane basis of business transactions. The logical beginning of such a transition is the elimination of waste.

Our province in this discussion is the glue industry, which itself is based on the recovery of waste. Although in this industry waste from various other industries is converted into a valuable commercial product, the process of conversion has not been free from the practice of wastefulness.

SAVINGS OF LABOR AND MATERIALS

As in other industries, savings have been made in labor and material in the last few years: savings in labor by the installation of various machines and rearrangement of equipment to facilitate flow of material through the various processes in the plant; savings in material by closer and more intelligent supervision of materials at each stage of manufacture. This control not only serves a very important part in preventing waste through decomposition, with consequent loss in yields, but has a direct bearing on improvement in quality.

The chemist has played a very important part in the glue industry, particularly in the last few years, and it is through his efforts that intelligent and systematic savings have been and are continuing to be made. There is still work for the chemist, however. The field is interesting and fertile enough to produce rich rewards for both the chemist and the industry.

One point at which a large amount of waste may be

eliminated is at the source of the raw material supply. Such raw materials for glue manufacture as are produced at packing houses and tanneries are merely by-products in these institutions and as such are not given the same consideration that the main products receive. To the glue maker it is a different story. These same byproducts are his raw material, and he is therefore vitally interested in their history and method of handling before they are received by him.

In many instances the improper handling of these materials at the source is due to lack of knowledge of proper methods. The glue maker is in a position to supply the necessary information, and in the interests of conservation is in duty bound to arrange for co-operation with whomever he is dealing. This has been done in isolated cases very successfully, and if the policy were carried out universally it would tend to eliminate waste and be a financial benefit to all parties concerned.

Chicago, Ill

Outstanding Causes of Waste in the Glue Industry

BY R. H. BOGUE

Industrial Fellow, Mellon Institute of Industrial Research

No single condition for waste in the glue industry stands pre-eminent, but three conditions prevail which, if eradicated, would constitute a seven-league stride in the direction of industrial economy.

LOSSES CAUSED BY POOR TECHNOLOGY

On the manufacturing side, the greatest losses arise through a careless disregard of certain principles that are known to constitute the most advanced practice in glue-house technology. Delay between the processes of boiling, evaporating and drying is most disastrous. The liquefying bacteria and molds which develop with awe-inspiring rapidity may bring the grade down sharply in only a few hours. The difference between the grade that should be attained with a given stock under the most favorable conditions and the grade as actually obtained should appear on the books as a technical loss, but this is not commonly done. Such a practice would furnish the most accurate index of plant efficiency. If the losses were necessitated through insufficient equipment, evaporator capacity or the like, there would be indicated in terms of dollars and cents the exact returns that an investment for such needed equipment would be expected to furnish.

CONSUMER OFTEN IGNORANT OF FUNDAMENTAL PROPERTIES OF GLUE

The wastes incurred by the consumer of glue through carelessness or an ignorance of the fundamental qualities of the material are of greater moment and are more to be deprecated than those committed by the manufacturer. The list of unsound glue-room practices is long. The measuring of glue rather than weighing may be fatal upon different lots of glue. The optimum concentration of glue for application upon different kinds of woods has not been sufficiently studied. Soaking is often carried on for too short a period; the upper portions are often dry; the soaking water is often so warm that bacteria injure the product. The temperature of melting is usually higher than necessary, and the melted glue is kept hot for many hours. Experiments show that a glue may lose in joining strength as much as 1,000 lb. per sq.in. by heating for twelve hours at 80 deg. C., or 5 per cent of its original strength per hour of heating. If maintained at a lower tempera-

ture (40 deg. C.), the bacterial decomposition will likewise result in a great weakening of joint strength. And unless the utmost precaution is used to keep all glue utensils perfectly clean, the liquefying bacteria that develop may become a most serious cause of joint failures. Higher joining pressures, evenly maintained, would result in the production of much stronger joints.

STANDARDIZATION AND SPECIFICATIONS BOUND TO COME

A standardization of the methods employed for the evaluation of glue and the expression of these tests in absolute terms is one of the most urgent of the present-day needs in the glue industry. Such a standardization could result only in good for the entire trade. The manufacturer could again enjoy a reputation based upon mutual rather than upon paternalistic confidence. The consumer would for the first time in history know just what he wanted and know when he received it. Glue would be ordered and sold upon a system of concise specifications, and a designated grade would refer to exactly the same thing, whether addressed to one company or to another. Manufacturers are reluctant to abrogate their long precedent of secrecy and competition through the art of salesmanship to an open competition based solely upon the quality-price basis; but public opinion and men of science are making the demand, and standardization is now a question not of whether it shall come, but of when it shall come.

Pittsburgh, Pa.

Wastes in Paint and Varnish Oils

BY OTTO EISENSCHIML
Manager, Scientific Oil Compounding Co.

All of the paint and varnish oil industries undoubtedly contribute their share of industrial wastes, but there are two representative industries which are particularly worthy of study. The first of these, the chinawood oil industry, is characterized by appalling transportation losses.

MUCH CHINAWOOD OIL LOST IN TRANSIT

Chinawood oil to a large extent is barreled in China and arrives at the Coast in the original cooperage. The waste on the boats due to leakage and breakage is enormous. Anyone that has received a shipment of chinawood oil has been perturbed at one time or another by the consistent discrepancies in the original gross weights and those that were marked on the barrels at the port of entry before the goods were re-shipped into the United States. On top of this, it is mighty seldom that a barrel load of this commodity arrives at its final destination without further serious damage. The writer has seen cars of chinawood oil arrive in Chicago time and time again with as many as ten and even twenty barrels completely broken in transit.

To make matters worse, a certain amount of soakage into the staves of the barrels takes place during the months that elapse between the barreling and the consumption of the oil. This waste amounts to from 2 to 11 lb. per barrel.

What a terrific overhead expense this means on the price of chinawood oil!

MANY LINSEED OIL PLANTS STAND IDLE

The second industry is the production of linseed oil, in which the greatest waste, it seem to me, lies in

excessive plant capacity. There are about three times as many flaxseed crushing plants as there are needed to take care of the linseed oil requirements of this country. The result is that most plants stand idle a great deal of the time, thus adding very considerably to the cost of production.

The remedy in the case of chinawood oil seems to be within reach. Elimination of wooden containers and more care in transportation, perhaps with a premium for those train crews whose cargoes suffer the least damage, should help matters greatly. At the present moment union rules are an obstacle to the last-named proposition.

So far as linseed oil is concerned no suggestion can be made. Repeated consolidations have failed in this respect and the permanent closing down of linseed oil mills has always been followed by the erection of new ones.

Chicago, Ill.

Improving the Paint and Varnish Industry

BY ROBERT S. PERRY
President, Perry & Webster, Inc., New York

The paint and varnish industry in Civil War times consisted of a few small factories for linseed oil, white lead and mixed paint.

Since the Civil War a continent has been occupied and a hundred million people across the far-flung miles have housed both a nation's families and a nation's activities.

To protect and decorate these new buildings of the great national expansion the paint and varnish industry grew with equal rapidity to enormous proportions.

As for the nation, so also for the paint and varnish industry, the half century of expansion prior to the World War was a period of effort toward increased profit from volume of output rather than from elimination of waste or possible savings in cost. The feverish activities of the World War period marked the definite end of this period for the paint and varnish industry. Maintained and increased success for any concern will now mean concentrated effort to improve commercial service, enhance quality of product and eliminate wastes.

FACTS TO BE CONSIDERED IN THE PAINT INDUSTRY

Waste savings must include investment cost in plant for a given output, as well as in labor, power and material. Better design for new factories, and careful engineering design, survey for reassemblage in present factories, are inevitable to meet the problems of investment, of labor and of power.

The recent developments and savings by leaders in the industry in finer grinding of tinting colors must be carried further and must be followed by those who have not yet availed themselves of the consequent better quality and conservation of these expensive materials. Standardization of colors like yellows will save great wastes.

Increased knowledge in colloidal chemistry and physics, and in the characteristics of paint as a plastic solid, as contrasted with its former study solely from the standpoint of a viscous liquid, directs us to question the possibility of ultimately transporting it from factory to consumer in a wrapper instead of in the expensive package of today.

We are now faced with the stupendous sums involved

in the present delivery to and destruction by the consumer of this container, which represents so large a percentage of the cost of the product. The white lead industry, with its use of about 99 per cent of all raw materials, is an example of the possibilities of waste conservation for the rest of the industry, and this high efficiency resulted from dust recovery as a sanitary measure.

RECENT IMPROVEMENTS IN THE VARNISH INDUSTRY

The heavy fume losses in varnish manufacture have now yielded to accurate knowledge of their nature and value, and about twenty leading manufacturers are now engaged in their recovery and use. The control and recovery of fume have led to control of fire risk and a new type of plant.

The new type of plant, the control of fire risk and the recovery of fume products have decreased varnish plant investment, cost of insurance and cost of product.

This new development of the past three years is rapidly transforming the varnish industry from a great waster to a highly economic and efficient industry.

New York City.

The Waste of the Soap Industry

BY J. H. CHESTER

Considering the manufacturing phase of the soap industry, the lay observer finds the waste extremely small. The processes are chemically controlled at every point and raw materials are purchased on absolute conformance with specification. In the factory, the nigger, or dark-colored material collecting at the bottom of the first-quality soap kettle, is drawn off and re-treated with the second quality batch. The nigger from this in turn passes through the laundry soap process, and the final residue from the laundry soap enters washing powders and cleansers. Washing powders, such as Gold Dust and Old Dutch Cleanser, were originally developed as an outlet to use up the foots from the cottonseed oil industry. They have a legitimate use in the household and serve the industry in the elimination of material wastes.

Manufacturing establishments are well located. Chicago, one of the principal centers, has the supply of fats from the packing houses and is sufficiently near the alkali supply from the Niagara district and mid-western sources. Principal centers east of the Mississippi River are economical locations for soap production and marketing. There is some economy of location on the Pacific Coast, where one or two plants have recently been established.

MATERIALS WITHOUT SOAP VALUE ADDED TO PLEASE THE PUBLIC

The salient waste in this business, however, is created through competition, where each producer, endeavoring to market his own particular product, has educated the public to desire transparent soap, perfumed soap, oatmeal, peroxide, witchhazel and other so-called medicinal soaps for the toilet. Embossed and lithographed art packages add to the expense. The production of transparent soap involves the incorporation of sugar, glycerine and sometimes castor oil. With one exception of foreign manufacture all transparent toilet soaps are cold made and require these substances, which are relatively very expensive and without detergent value.

Perfumery in soap is likewise cheapening in its use and sold at absurdly high prices. So a double waste is incurred with the purchaser paying a higher price for an article having no added soap value for the increased weight. The medicinal soaps do not contain enough of the constituent to warrant so branding and lead to a sense of false security. No germicide incorporated in soap can be as efficacious for removal of bacteria as can mechanical friction on the skin.

There is no distinct line of demarkation between toilet and laundry soap, since one merges into the other by nature of the manufacturing process. Many laundry soaps are put on the market heavily weighted with inert fillers, such as starch, silica and clays, which have no scouring or detergent value. Of course where silica is incorporated admittedly for scouring purposes there is no imposition on the public. The price paid for transportation cost on inert materials mounts to a large figure in the United States each year. On the contrary, white soaps having alkali fillers like soda ash or silicate of soda perform a function in softening the water.

PURE SOAP LAW WOULD PROVE BENEFICIAL

The best possible compound for soap is made by processing high-grade fats with first quality alkali. But toilet and laundry soaps should be purchased on the guaranteed soap value. Where it is necessary to soften hard water the soda ash or other alkali should be added separately. Were an act similar to that governing pure food and drugs enforced for soap products, it would work an economic benefit alike to users and reputable manufacturers.

There is no excuse today for low titer oils not being used, because they may all be hydrogenated to any degree of hardness desired. One form which research is now taking deals with the possibilities of the saponification of mineral oils. There will no doubt be discoveries from research laboratories which will permit of even better and cheaper methods of manufacture and treatment of raw materials, but after all is said and done, the greatest waste lies in the misleading of the public by the manufacturer overanxious to outstrip his competitor in the disposal of products.

How the Fertilizer Industry Can Prevent Wastes

BY CHARLES H. MACDOWELL

President, Armour Fertilizer Works

In common with all commercial ventures, the fertilizer industry has many opportunities for waste and often makes the most of them. It is a heavy chemical industry, manufacturing and selling plant food on a guaranteed analysis. It receives no pay for overruns and is docked for under-analyses. The old-time superintendent was sure he could determine the analysis of a variable material by looks and taste. He was wrong, but there are some old timers still at the helm. They refuse to adopt chemical control. Study of state inspection reports shows many costly overruns and comparatively few underruns. The industry gives away millions of dollars of plant food above reasonable safety provisions.

STRICT CHEMICAL CONTROL NEEDED

Plant losses begin with incoming material purchased on an average-lot-analysis basis. The values contained in one car often differ from those of another. This variation should be known. Shrinkage in weight in

handling and manufacturing starts at once. Average shrinkage should be ascertained and figured. Sulphuric acid yields may be good or bad, with niter consumption high or reasonable. The relation of iron to alumina in phosphate rock affects the availability and mechanical condition of acid phosphate. Fine grinding has much to do with obtaining low insolubles. Different rocks require varying quantities of sulphuric acid to obtain lowest costs and highest availability. Knowledge of what's going on in a factory can be obtained only by a strict chemical control.

In formulating mixtures a procedure based on careful weighing of ingredients of known analysis through mixing, and check analyses after mixing, including further balancing if needed, is the big enemy of waste in the mixing department and the good friend of profits. Again chemical control is the answer.

ACCURATE WEIGHING AND CAREFUL INSPECTIONS PAY

In handling incoming ingredients and outgoing finished product the man at the scale, if he is careless, makes dents in black figures during good years and increases the red in bad ones. Under normal conditions the industry fills 90,000,000 sacks of product. An overrun of a pound to the bag (and an over-industrious worker filled with speed mania can easily accomplish this) would mean giving away 45,000 tons of product worth fully \$1,350,000.

Avoiding waste in manufacturing comes from knowing what you sell as well as what you pay for, keeping fully informed as to your work and yields, careful inspection of machinery to avoid breakdowns and to save power consumption, accurate weighing, avoiding false motions in labor handling and keeping your superintendent advised as to costs on differing outputs that he may cut his cloth properly.

POOR COST-ACCOUNTING DISCREDITS THE INDUSTRY

As to cost-accounting: Like the overcoat in the expense account, all cost items get into the ledger some time and often too late for safety. Known costs are checked out daily, but unless deposits are annually made for hidden items of cost the unwelcome "no funds" notice comes to hand too soon for pride or for financial comfort. Often charges for interest on investment, or on stocks, are not taken into consideration in plant-accounting. Buildings, machinery and outside equipment are subject to heavy depreciation, and charges should be spread over the life of the plant to take care of these costs. Obsolescence is an item few makers consider. Depreciation reserves figured annually should be set up for the unusually heavy replacement year.

Companies that do not figure these items properly are fooling themselves and are apt to accept business on a basis of actual loss when they think they are making a profit. Such sales demoralize markets and discredit the industry. Steps are being taken by the National Fertilizer Association to work out a rational cost-accounting system which should show up much of the waste of manufacturing. This, together with chemical control and rigid plant and process inspection, should do away with many losses and tend to stabilize conditions. Do the thing right, know that it is being done right, know what it costs to do it and many present-day ills will disappear.

Chicago, Ill.

The Lumber Industry—A Flagrant Waster

BY EARLE H. CLAPP

Assistant Forester, U. S. Forest Service

American industry and the American public in their use of forest products have been and still are as prodigal as Nature herself. Not more than one board foot appears in finished lumber for every four cut in the woods. Two of the four are left in the woods or fed into the sawmill burner or are lost in seasoning before the stage of rough-seasoned lumber is reached. The third foot disappears during the manufacture of the finished product.

Even greater waste in manufacture is not uncommon. The hickory-handle maker buys two tons of lumber and sells 400 lb. of handles. In many furniture and chair plants unskilled labor plus unskilled supervision net only 70 or 50 or 35 per cent of the lumber received. Similar wastes characterize most all the other wood-utilization industries.

ENORMOUS WASTES DUE TO MISUSE AND TO FOREST FIRES

The question may be approached from another standpoint. The building trades alone use annually \$200,000,000 worth of timber in general construction where strength is a factor, and have only begun to consider working stresses. Much of the railroad claims bill of \$100,000,000 for damaged or lost goods should be charged to faulty containers. Fifty million dollars may cover the annual loss from poor seasoning of lumber. The development and use of preservatives in timbers exposed to decay could be made to save an enormous drain, equal to the annual loss from forest fires. Fire retardants and better construction could likewise largely reduce the \$200,000,000 annual bill for fire losses in buildings.

Our losses from forest fires have for the past ten years averaged 1,000,000,000 cu.ft. Furthermore, we allow 81,000,000 acres of forest land to remain an idle waste year after year and even add to it annually something like five to eight million acres. We are satisfied with one-fourth of the easily obtainable growth on 237,000,000 acres additional of cut-over and burned lands.

Much of this enormous waste is pure prodigality. When we have so much, why worry about waste? There is more money in wasteful than in careful use. We have not yet spent our inheritance and we will not go to work until we feel the pangs of hunger. Many seem to think it will be time enough then, provided that Yankee ingenuity has not found substitutes for wood by that time. Excessive waste in the forest industries has first, therefore, resulted from the very wealth of our resources.

BETTER KNOWLEDGE OF THE PROPERTIES OF WOOD A SURE REMEDY AGAINST WASTE

The second outstanding cause is our ignorance of wood and its products. Wood has been taken as a matter of course—nothing more has been thought necessary than the rules of thumb handed down from generation to generation. Only during the last decade has there been any real perception of the fact that we are dealing with a complex and variable substance, and of what this means practically. We are beginning to learn that knowledge of the strength properties of wood makes possible great economies, even in so elementary a matter as the making of boxes, for example. Knowledge of the physical properties of wood will solve

our seasoning problems. And finally, we can make the chemistry of wood assist in the utilization of vast quantities of material now waste, not only for pulp and paper, alcohol and other familiar products, but also for purposes now undreamed of, as is exemplified by the recent discovery of a method for converting sawdust into stock feed.

Washington, D. C.

More Pulp Per Cord of Wood—Why Not?

BY JOHN D. RUE

In Charge, Pulp and Paper Section, Forest Products Laboratory

The pulp and paper industry stands seventh in the list of great American industries. In 1920 over 7,000,000 tons of paper was produced in the United States, in the manufacture of which 6,114,072 cords of wood were consumed. This wood cost the manufacturers over \$116,000,000. One of the prominent examples of waste and inefficiency in this country is found in the present methods of handling and utilizing our forests. The pulp and paper industry is a large contributing factor in the production of this waste, since 8 per cent of the annual cut of timber goes into the manufacture of paper. Each cord of wood cut contains a certain quantity of potential paper-making material. When manufactured into ground wood pulp, all but the water-soluble portion, or approximately 96 per cent of the wood, exclusive of the bark and knots, could become paper. When manufactured into chemical pulps, probably between 55 and 60 per cent of the wood could become paper. Anything less than these amounts really constitute a waste. Let us consider the causes for such wastes and how far they might be avoided.

It is comparatively easy to point out the location of the losses, but, unfortunately, the methods of measuring the wood used and the pulp produced, especially the former, are so inadequate that no real knowledge of percentage yields can be obtained. Such information is most essential, however; for an accurate knowledge of existing conditions is prerequisite to improving these conditions.

WASTE CAUSED BY DECAY DURING STORAGE

If we start our consideration with the pulpwood after it has been cut, we will find our first source of loss in decay during storage. A certain amount of decay in the wood as received must be expected, for the pulp industry cannot compete with the lumber industry for the finer grades of wood. Lack of proper care in handling and storing is responsible, nevertheless, for large decay losses. The wood loses in weight, causing a proportionate loss in the possible yield of ground wood pulp as well as a loss in the quality of the product. Furthermore, the destructive organisms have a selective action on the cellulose, so that the potential yield of chemical pulp is reduced. Losses from the decay of pulpwood and wood pulp are estimated at at least \$5,000,000 per year, and could to a large extent be prevented, provided more were known about proper methods of handling and storing the various species, and more of that which is known were put into practice. Investigations of preservative treatments for ground wood pulp have already indicated most encouraging results in the prevention of decay during storage.

In the grinding of wood losses are met with on account of the production of excessive amounts of fine wood flour and of large slivers. More efficient control, as well as improvements in the quality of the stone and

in its care during operation could do much to lessen these losses, which amount to over 5 per cent, or 75,000 tons per year, valued at \$3,000,000.

IMPROVING THE METHODS OF PULP MANUFACTURE

The fundamental object in using chemical processes in the manufacture of pulp is to produce a pulp of greater durability and of higher quality than is possessed by ground wood pulp. Approximately 55 to 60 per cent of the weight of the pulp consists of cellulose, and it is reasonable to expect that it should be possible to obtain this amount of a white pulp product. Higher yields should be obtained when a less pure product will suffice. As a matter of fact, in practice less than 45 per cent of the wood is obtained as high-grade pulp, or less than 75 per cent of the potential yield. In other words, the wood consumed during 1919 should have produced 600,000 tons more than the 2,000,000 tons actually obtained, which on a very conservative estimate would represent a value of \$30,000,000. It would not be fair to the pulp manufacturers to estimate that this loss is entirely or even largely due to inefficient methods of operation, although it is true that through a more thorough system of technical control much saving could be realized both through improved yield and through improved quality of product. It is fair, however, to charge the industry with a large portion of this loss, because it has failed to prosecute vigorously the scientific investigations necessary to unfold the underlying principles of the processes. Such knowledge is fundamental to the rapid improvement of pulp manufacturing processes and to the design of efficient plants and equipment.

It is a regrettable commentary on the industry that the past fifty years has seen so few changes in the pulping processes. With the exception of an increase in the size of units and in the rapidity of production, pulp manufacture today stands practically where it stood during the last quarter of the nineteenth century. There are evidences, however, of an awakening to the need for intensive investigations along these lines which give promise of greater progress in the future.

MORE FAVORABLY LOCATED SPECIES MUST BE USED IF POSSIBLE

Any discussion of the inefficient utilization of wood in pulp and paper manufacture would not be complete without emphasizing at least one other factor, a factor which when fully appreciated is most startling. Fifty-six per cent of all the pulp wood consumed is spruce. If we include with spruce hemlock and balsam fir, these three species constitute 77 per cent of the entire pulpwood consumption. The significance of these facts becomes evident when we realize that the supply of these species comes almost exclusively from the northeastern section of the United States, and that it is estimated that this supply constitutes only 3 per cent of the entire wood supply of the country. The drain on this limited number of species is causing their rapid depletion. Pulp mills which were a few years ago in the heart of their pulpwood supply are now forced to haul their wood long distances and in many cases past large stands of available timber, which, however, are considered undesirable for pulping. This state of affairs means lower profits to the manufacturer and higher prices to the consumer. Here again intensive investigation and research are needed to point the way to economic means of utilizing more favorably located

species. In a field of such wide application and universal interest the highest degree of co-operation in such investigations is desirable, if not imperative.

NORTHERN PINES THE MOST PROMISING POSSIBILITY

Species that are to meet satisfactorily the demands for pulpwood must be favorably located with respect either to present mills or to the pulp markets. An increased supply of spruce, hemlock and fir can be found only in the far West; too far from present mills and too far from present pulp markets to warrant the extensive building of new mills.

A goodly supply of hardwoods is available especially in the Central and Southern States, but the shortness of their fiber greatly limits their field of usefulness. The pines, however, still remain as an important possibility. If the Northern pines could be satisfactorily used, the supply of pulpwood to the mills now using spruce, hemlock and fir would be immediately doubled. Five times as much more pine is available in the Central, East Central and Southern States. These localities would be within range of pulp markets and the supply of pulpwood could be obtained without undue competition with the lumber industry. Here again the one outstanding need is for intensive research to blaze the trail to successful utilization.

Sins of omission are quite as grave as those of commission. The fact that the industry has failed to provide for an early solution of these problems does not relieve it one whit from the responsibility for the inefficiencies and waste which this failure involves. It is a matter for great encouragement that the leading organizations of the industry are turning their attention to these problems. The need is urgent, and procrastination spells catastrophe.

Madison, Wis.

The Lack of Team Work in the Wood- Distillation Industry

BY FRANK J. ROOT

So much has been published on the huge loss of sound wood in form of forest waste and mill waste that one may now merely call attention to the fact that it is one of our foremost extravagances.

In the manufacture of wood-distillation products in the United States good body wood in the form of cord wood has been used at an average rate of over a million cords annually for the last twenty years. This cord wood has been so increasingly expensive and hard to obtain that many makers have curtailed an otherwise profitable production, while some have entirely suspended operations.

USE OF MILL WASTE RETARDED BY LACK OF CO-OPERATION

The major problem during these twenty years has been to find a method whereby the vast quantity of mill waste might be made to replace the disappearing cord wood. This effort has indeed been a battle royal, with three chief participants: (1) The mill owner; (2) the wood-distillation operator, and (3) the technical man. There seems to exist every economic reason why these three should work in entire harmony, but instead they treat one another with suspicion and do not seem able to speak the same dialect. The sawmill owner pleads he is not a chemical man and hence will have none of it. He also holds his waste at prohibitive figures. The wood-distillation men as a class stand

aloof from advancement, not only refusing to aid but insisting that their own antiquated methods cannot be improved. This is humorous in view of the fact that their yields per unit of wood carbonized have been steadily declining until they are now 30 per cent below the good yields of twenty years ago. Their sporadic attempts at improvement have been for the most part ill-advised repetitions of well-known mistakes.

CAUSES OF FAILURE SHOULD BE STUDIED

What, then, is the answer? Suppose a case in which John Doe spends \$80,000 or \$100,000 in an attempt at betterment, which fails utterly and the plant passes to the scrap heap. A little later Richard Roe (who does not know John Doe) feels the urgency of improvement and begins a similar campaign, carefully avoiding any contact with the lamented John or his history, which he dismisses with the terse term, "failure." Roe proceeds until he, too, is in deep water, only to find he has in effect repeated John's error.

Obviously, this economic waste may be avoided by properly compiled records which shall include failures as well as successes. It may not be pleasant to work in a morgue, nevertheless the resulting knowledge of how the patient died may save the next case. The only way the so-called human race progresses is by beginning where the other chap quit. Refusal to do this results in some of the difficulties from which this industry suffers.

THE SAVING FROM BETTER RECOVERY OF WOOD-DISTILLATION PRODUCTS

Another phase of this interesting history may serve to illustrate the lack of team work: Each cord of wood carbonized yields as an unavoidable byproduct, 12,000 to 15,000 cu.ft. of gas. When leaving the retort this gas carries with it all the liquid values, including the wood alcohol. To reclaim these values from the gas an ordinary water-cooled surface condenser alone is employed. This serves to remove a large portion of the liquids, but unfortunately not nearly all. The gas mass, still saturated to its dew point with both alcohol and acetic acid, goes directly to the fireboxes and is burned as fuel.

About twenty years ago a method was worked out whereby these liquids were reclaimed from the gas and at the same time the vapor tension on the retorts was accurately controlled, the net saving amounting to a 10 per cent increase in products made. This work was done on a commercial scale and installed in a small group of plants, where it continued to make its regular 10 per cent saving year after year.

With a record like this one might expect to see every plant similarly equipped, but sad to relate the number so equipped has never been materially increased.

The loss so incurred may perhaps be best visualized if stated in terms of trees: each year the industry thus unnecessarily cuts 5,000 acres of good standing timber. In the twenty years under discussion it has cut 100,000 acres.

This protracted sacrifice appears to the writer to be in the same class as the drain on the productive land of India by the keeping of vast herds of "sacred" cattle which produce nothing. We condemn the Indian's attitude. What shall we say of the American parallel situation? A small amount of team work by the parties interested would soon correct this waste and avoid another twenty years of extravagance.

Defenseless in War

And Laggards in Peace

THE present is a historic moment in American chemistry. True, the meeting of the American Chemical Society, now in session in New York, is incidental inasmuch as it is a semi-annual occasion and the exposition is established as an annual affair. But never before was there so much at stake for chemistry in America. The reason for this is because we are momentarily weak in the weakest link of our chain.

As a nation we are a lazy people. Nearly every Yankee invention from the sulky plow to the sewing machine was designed originally to make less work and that easier. We'd rather sit down than stand up and when we search our hearts we find that most of us aspire first of all to wealth for the purpose of ease. We have let the wish become father to the thought and, having grown rich as a nation, we have, rich and poor alike, adopted luxurious habits of mind. We think hard only once in awhile; the rest of the time we let things drift until the miseries bank themselves up against us. Then we have to hustle when it is almost and sometimes quite too late. It was so with the Civil War, with the German war, with free silver, with American shipping, with the petroleum industry of which we are losing the leadership, and we are now at the parting of the ways in chemistry.

A number of signs that everyone can recognize point to this danger. The widespread devastation of research laboratories by incompetent administrators of chemical industries is one of them. Chemical industry differs from all others in that it cannot be permanently standardized. The standard of today may well spell failure tomorrow. Research must always be years—sometimes even a dozen years—ahead of the game. Unless not only administrators but even stockholders understand this, chemical industry cannot thrive.

The effort to kill the U. S. Chemical Warfare Service was another close call. We have to thank the enlightenment and the perseverance of a very few Senators and Representatives in Congress that this leading feature of national safety was not utterly destroyed. It has now been reduced to such a skeleton that only by the greatest intelligence in leadership can it be maintained. The removal of General FRIES and the appointment in succession of someone of the unscientific type of mind of General PEYTON C. MARCH, for instance, competent soldier though he may be in other respects, would destroy it in short order.

The dye industry is the bulwark of organic chemistry. Chemists and textile manufacturers and dyers and finishers all know that the price of dyes themselves has the least bearing on the cost of finished goods. They know that every dye that makes for fastness against light, wash, bleach, wear and perspiration that was available before the war is available today

by direct purchase on the market or by importation under license. They know that the bulk of the costs of dyeing and finishing is in labor and time and not in dyes. And yet we find on all sides, repeated *ad nauseam*, the deliberate lie that improperly dyed goods are inferior because American-made dyes are not good. This is not true and manufacturers know it. When the coloring is inferior, it is because with the high cost of labor in American dye and finishing houses, it is cheaper to make it so. That is the sole reason. The cost of the dye itself is negligible. At the same time Congress has thrice refused to provide for the continuance within our borders of this industry, which is as essential to our national defense as the United States Artillery. If Congress does not learn this fact before the end of the year, the industry will be lost.

We could continue the enumeration of these danger signals at greater length if we were so disposed, but we shall merely add the note that the Employment Bureau of the Chemists' Club is overwhelmed with applicants for positions, whereas there are but few vacancies to fill. The applicants include men of splendid attainment and capacity. The very time when they might be doing the kind of work that reduces the cost of production or improves the quality of products they are sent away. We know of one great chemical works that let about 500 of its laborers go because there was no market for its goods. It was in the same boat as other manufacturers. But it kept its research laboratory in more intensified activity than before. "Bad times have hit us," said the president, "but we need our chemists. We need them more than we need our accountants, and we shall not close our research laboratory until after we close our office." Incidentally it may be said that the products of this plant bear an enviable reputation for quality.

Perhaps with the spread of the doctrine of relativity we may gain a larger sense of what time is. Our present disposition is to think that "any time will do." But any time will not do. We must do some things now, today, or the opportunity will pass. We must change a number of our ways. We must reorganize research by re-establishing it, not only where it has been given up but elsewhere. We must hearten the chemists engaged in their work. We must enlarge and spread chemical understanding and sense in the offices of works and among their boards of directors. We must teach our legislators the meaning of chemistry and its amazing ubiquity, from the farm to the fireside. These are our tasks today, tomorrow, next week, next month, before the year is over. We are indeed at the parting of the ways. We must conserve chemistry in America. It is the gospel of industry and the protector of nations. Without the pure science we cannot apply it and without applied chemistry we shall be defenseless in war and laggards in peace.

The Electric Furnace and Sound Castings of Pure Silver

THE introduction of the electric furnace into the United States Mint and into precious metal foundries is in itself a notable event; and it seems likely that due to the high efficiency of the operation and the excellence of its products the electric furnace will attain supremacy in this as well as in other branches of non-ferrous metal melting. In changing from crucible melting to electric-furnace melting it was necessary to take into account the natural properties of silver, particularly pure silver. The latter in the molten state will occlude, absorb or combine with 22 volumes of oxygen, giving rise to the familiar phenomenon of "spitting" or "sprouting" due to the escape of the imprisoned gas as the metal cools. Whether the oxygen is combined, as MUSPRATT believed, or merely occluded has never been settled; however, metallurgists have resorted to various expedients to eliminate "sprouting," as otherwise it is impossible to make sound castings fit for rolling or stamping. Accordingly it has been common practice to use an air-tight covering of molten salt or a covering of charcoal. There are, however, serious objections to coverings of this kind.

In introducing the electric furnace into the silver foundry steps were taken to eliminate all coverings and reduce the metal losses to a minimum. The successful culmination of tests to this end are recorded by Mr. HERLENIUS elsewhere in this issue and will be presented also by Mr. DEFRIES next week. The interesting and novel feature of the work consists in the introduction of an iron block into the silver bath. This practice serves a double purpose: First, that of a heat equalizer; and second, that of an oxygen "sponge." The idea is so simple, and therefore the more valuable, that one wonders that it was not suggested long ago. But with the empirical results well in hand, it is possible to offer some thermochemical comparisons. The specific heat of iron throughout the temperature range of melting and casting silver is twice that of the precious metal. Again, the heat of combination of iron with oxygen is about ten times that of silver with oxygen. Furthermore, the iron oxides are very stable, whereas the silver oxides are very unstable.

The metallurgist may see in the principle of the iron sponge process a certain parallelism with the Parkes process of silver refining. It will be recalled that in this process advantage is taken of the fact that freezing zinc and lead are mutually insoluble, or very nearly so, while silver at the same temperature has a decided affinity for zinc and only a slight affinity for lead. Similarly, in the iron sponge process, molten silver has little affinity for iron, while oxygen has a decided affinity for iron and only a slight affinity for silver. The iron sponge process is so extremely simple and has given such excellent results in the case of silver that it seems likely the underlying principles may be applicable to the making of sound castings of other metals—for example, copper. 'Tis true that the old Lautenthal foundry used to place a wrought-iron ring on the molten silver to prevent the spattering of the silver sulphate during the Roessler refining process. Others have employed iron rods to stir the molten silver. But no one, we believe, has ever before introduced metallic iron into the molten bath, as a stabilizer of heat and an absorber of "noxious" gas. They even have told us that oxygen is insoluble in iron!

Wastes in the Iron and Steel Industry

IT IS only about twenty years ago that a steel mill was abandoned, having separate foundations for the shafts and cylinders of some of the engines. Less than thirty years ago a Corliss engine was considered far too delicate a machine to be used in a rolling mill. The industry has made wonderful progress in the past quarter century, more rapid progress than in any previous period. The best practice today is not far from the best practice it is now possible to propose. The best practice is not universal, but where it is not followed the cause is lack of capital rather than lack of knowledge or desire. There is little to criticize or suggest as to the individual manufacturing interest.

The iron and steel industry considered as a unit, however, presents cases of tremendous losses. The losses referred to are due to distributed ownership of facilities that should be under one ownership and management. One great loss is due to the existence of what are known as "merchant" blast furnaces. Another loss is due to the use of the beehive coking process instead of the byproduct process. The merchant furnaces make between 25 and 30 per cent of all the pig iron. As a rule it is not feasible for them to operate a byproduct coking plant, on account of the smallness of the operation; that is one loss. The furnace, if it has reasonably good practice, uses economically all of its gas that it needs and wastes the rest; that is another loss. A third loss arises from the furnace being idle a very considerable percentage of the time. If the steel mills, which consume between 75 and 80 per cent of all the pig iron made, should make all the pig iron, they could conveniently stock malleable, forge and foundry grades in dull times. It is disadvantageous for them to stock such iron as they use themselves, since they lose the advantage of "direct" or molten metal. With one or two interesting exceptions, all the merchant iron now made is delivered cold, so that it is iron that could readily be stocked. Steadier operation of blast furnaces would result. The recent past has given an impressive lesson of the desirability of finding an operation for steel works blast furnaces in dull times, as well as an excuse for operating attached byproduct ovens. At some steel works in the past six or eight months there has been a painful accumulation both of byproduct coke and of pig iron, partly because blast furnaces had to be operated as gas producers. The gas was needed, the pig iron was not needed.

It is a debatable question whether an economy would be represented by the steel-making industry carrying its products to a greater degree of finish. The fact that some steel makers have gone farther while others have not shows that the matter is debatable, and it is easily seen that there has been no uniformity of counsel. One steel company builds freight cars. Another, and larger, company has kept away from freight cars but makes well derricks. Another steel interest does not fabricate the sheets it rolls but does make railroad spikes. As a rule steel mills have tended to avoid fabricating their rolled products, because they wished to avoid the appearance of competition with their natural customers, but in order to "expand" have added new lines of rolled material instead of following the original line to a greater degree of finish. On the ground of economy many products could be fabricated much better by the mill than by the mill's customers.

Would the ZR-2 Have Been Saved by Helium?

SOME authorities answer this question "Yes." Some say "No." Others express a noncommittal "Perhaps." But however the question is answered, anyone who knows the facts admits that there has never been enough helium produced to have filled the ship even if all of it could have been assembled for use in the fatal trial flight.

Industrially the question of real importance is, "What is the influence upon our national helium program of this much regretted disaster? It is immaterial whether it was a failure of framework, an explosion of gas, or a gasoline fire which was the original cause of the crash. All contributed to the final result, but if helium had been present instead of hydrogen at least one element of the disaster would have been eliminated. In other words, as expressed by one Government scientist, "The disaster is another argument for the advancement of the helium program."

At present there is available for helium studies from Army appropriations a quarter-million dollars. The Navy appropriation, which is made in one general fund for several projects, will provide an additional \$400,000 if it is prorated according to the original requests for funds. However, this sum can be augmented if the Secretary of the Navy should deem the helium work of greater relative importance than the other projects which must be cared for from this general fund. But it is unlikely that helium will be considered sufficiently important to increase the allotment for it to a total of \$1,600,000, which is the sum requested by the Helium Board. This would practically stop other essential work in the lighter-than-air service. It seems certain, therefore, that the Government work will progress much less rapidly than was deemed desirable by the Army and Navy officials who prepared the estimates unless Congress should come to their relief.

Helium is a typically American resource. Numerous natural gas fields are known by the Bureau of Mines where recoverable quantities of helium could be obtained by a process which is already a demonstrated success in the plant at Fort Worth, Tex. No other nation has such helium reserves. Therefore, so long as helium production does not result in export, America will have exclusive advantage of this non-flammable balloon gas. Indeed, this element of exclusiveness is one of the most convincing arguments for the further development of our helium projects, expensive though they be.

It is too soon to say what the official conclusions will be on the question whether increased impetus shall be given to the helium program or not. Officials of the Army, the Navy and the Bureau of Mines all wish to reserve judgment in the matter a bit longer in the hope that we can learn more of the causes and the significance of the catastrophe. However, certain fundamental facts can be clearly set forth at once. These are most strikingly given by R. B. MOORE, chief chemist of the Bureau of Mines, who from the first has been intimately associated with the development of the helium resources and is still in charge of much of the most effective work being done by the Government in this field. He says in effect:

"For the price of one battleship it would easily be possible to maintain and operate permanently six of the most modern helium-filled dirigibles which the best

talent of America could design. Included in this program would be adequate provision for reserves of helium-bearing natural gas, adequate facilities for generation of the needed helium, its recovery and repurification, and generous allowance for needed fundamental research in physics, chemistry and engineering. The question therefore is, 'Which will contribute most to American security and defense, one additional modern first-line battleship or an elaborate program in the field of non-flammable, lighter-than-air craft of wide-cruising radius, tremendous powers of offense and almost unrivaled ability in defensive observation?'"

It is too much to expect that the Government will provide thus extensively at once. The first requirement is to obtain and conserve in adequate degree the most important fields where high percentage helium-bearing natural gas is found. Fortunately this means saving gas which is generally least valuable for commercial sale, because high helium content means also high nitrogen content and low heating value. Second in importance is the support of small-scale research, particularly the work of the cryogenic laboratory at the Bureau of Mines and the corresponding activities which logically will supplement that work. In the third place, one must then ask for plant-scale research, including perhaps the necessary investigations to make the Petrolia plant using the Jeffreys-Norton process a success, if this proves feasible. Next will be the provision for plant operation on a large scale and large-capacity storage of the gas. Finally will come the time when construction of the several airships for use with helium can be undertaken with the surety that adequate supply of gas will be at hand for their regular operation. In the meantime, of course, much work on design of these vessels and a limited amount of experimentation on their construction would be expected. Unfortunately progress on this extensive program is likely to be slower than all of us would wish, but so long as definite progress is constantly being made, and along right lines, every encouragement should be given to the Government in its helium projects. That the progress will be along the right lines seems assured, for Army, Navy and scientific bureau specialists are co-operating closely through the Helium Board and no chance for constructive criticism and advice is being ignored by any of these agencies.

And AGAIN.

What Is a Chemist?

THE question will not down, and sometimes out of the mouths of babes and sucklings come—side-lights. In the New York office of a large heavy chemical manufacturing concern there is a lad of fourteen who shows originality, although it is scarcely of the type that indicates the possession of the research mind. One morning not long ago he appeared with great, horn-rimmed spectacles. He was asked if he was having trouble with his eyes, and he replied that he was not. "I am studying," he explained, "to be an acid expert."

If we are "very much what we think we are," then this cheerful youngster is doubtless already "very much" of an acid expert. And yet even this does not fully answer a question which has been teasing us for a considerable time and to which we can get no satisfactory answer. It has become a chronic conundrum. Why can we not get general trade specifications for heavy chemicals? Every effort thus far has been unsuccessful.

Readers' Views and Comments

The Constitution of Gas Atmospheres in Aluminum Alloy Melting Furnaces

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 60 of your issue of July 13, 1921, in an article by Robert J. Anderson and J. H. Capps, entitled "The Constitution of Gas Atmospheres in Aluminum Alloy Melting Furnaces," there appears some discussion with regard to the toxicity of gases emanating from electric furnaces used for this purpose.

Carbon monoxide is, of course, extremely poisonous, and if all of the carbon monoxide produced in such a furnace were to be discharged unchanged into the foundry atmosphere, a serious condition would probably result. As a matter of fact, such carbon monoxide as does leave the furnace through various vents is at an extremely high temperature in the case of arc furnaces particularly and, as a result, burns to carbon dioxide as soon as it strikes the air. This is obvious to anyone who has watched the operation of an electric arc furnace for any length of time, whether this furnace is melting steel, brass, aluminum or any other metal whatsoever. I believe that any user of electric arc furnaces will agree that it is practically impossible for any appreciable amount of carbon monoxide to escape from his furnaces into the atmosphere of the foundry.

With respect to cyanogen the situation is, of course, somewhat different, but the authors state in this same article that they have been unable to detect cyanogen by chemical methods even in the atmosphere of the furnace itself where it would be most concentrated. Although it is occasionally possible to detect the odor of cyanogen in the neighborhood of an electric furnace melting aluminum, this gas is evidently present in such exceedingly small quantities that no unpleasant results are to be expected. As a matter of fact, as the authors state, there is absolutely no record of injury to health from electric-furnace gases in any commercial installation despite the fact that electric furnaces have been in use for many years in the melting of both steel and brass.

Culture in Technical Education

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial on "Culture in Technical Education" in the number for July 20 overlooks one important element in the problem under consideration. At the end of any four-year course the father of the boy taking it has had frequent reminders of the fact that college courses are expensive. In very many cases the family resources have been strained by reason of this. To add two more years to the total would in not a few cases make such a course impossible for some of the best men applying. I think this has had much to do with the present condition of things, and I know of one case where this was the controlling thought.

Given a student who has enough perseverance to give six years to such a quest, there can be no doubt that six years are better than four. It seems to me, however, that it may be worth consideration whether some of the additional courses desired may not come into the

college preparatory course. I cannot rid myself of the impression that too much of the pre-college time is poorly applied, and, in some instances, almost entirely wasted.

It is also true that much time in college is wasted. Not a few college professors are extremely poor teachers; in some cases men remarkable for work as investigators have shown an utter lack of teaching ability. I have come to think that college professors should be classified as teachers and investigators, and that the first class should be required to take normal school courses before teaching. Some college professors I have known have failed to understand that there is such a thing as psychology. The appeal to reason is their only appeal, and this is very seldom effective.

Studies in Colorado Shale Oils

To the Editor of Chemical and Metallurgical Engineering

SIR:—In reading the interesting article by A. J. Franks, in your July 13th number, on "Studies in Colorado Shale Oils," we were rather surprised that after he had discontinued the use of the cumbersome Waters method for the determination of sulphur in his samples of shale oil, he turned to the use of the Parr sodium peroxide bomb.

In Technical Paper 26 of the Bureau of Mines the results of an investigation of the various methods of sulphur determination of oils are shown. The Bureau went into this matter very carefully and they found that the use of an oxygen bomb gave a method for sulphur determination of oils and combustible materials which was "accurate, rapid and reliable."

The Parr oxygen bomb, made of the so-called illium alloy, is particularly adapted to this work and if one does not care to secure the bomb manufactured for the calorific determinations, there is a smaller size which is turned out especially for sulphur determinations.

We believe that Mr. Franks would have saved himself considerable work and time had he used an oxygen bomb for his sulphur determinations.

RALPH R. MATTHEWS.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reply to Mr. Matthews' comment I wish to bring to his attention the fourth and eighth paragraphs of my paper, in which he will find, among other relevant statements, the following sentences: "Since it is beyond the scope of this paper to discuss the relative merits and defects of different methods for determining sulphur, only the two which were actually tried will be given consideration." "Since a complete discourse on this subject would be too long to be included here, only the main points will be considered briefly, a fuller and more detailed discussion being reserved for a later paper."

My paper dealt primarily with the amounts of sulphur in shale oils and their fractions, not with methods for determining sulphur. A comprehensive discussion

of the latter subject would have required much valuable space. Such a discourse could not have been justly included. I reserved it for a later paper which has been in preparation for some time. Hence I did not choose to present all the data I had, nor any but very general and brief reasons for adopting the sodium peroxide fusion method. Under these circumstances I do not feel that anyone is justified in making critical suggestions or remarks concerning the methods I used. It is entirely sufficient that the results given in my paper are accurate.

Mr. Matthews' letter conveys the impression that I am not aware of the fact that there is such an apparatus as the Parr oxygen bomb for sulphur determinations and that there are advantages attending its use. I can say with pride that I am a former pupil of Prof. Parr, and am very well acquainted with the virtues of all standard apparatus of his design.

Although I expect later to discuss the subject in detail in a special paper, I will defend my choice with a few brief remarks, since the wisdom of my decision has been questioned. Permit me to repeat the requirements which a method must meet in order to serve satisfactorily for the large number of determinations which we were called upon to make in the course of our research:

1. The cost of the apparatus should not be great.
2. The results must be dependable and as accurate as possible.
3. The determinations should require a minimum amount of time.

If analyses are to be made economically, at least two bombs are required. The cost of a single oxygen bomb and the necessary accessories is far in excess of that for two peroxide bombs. Hence where expense is a factor the use of the former is out of the question.

In so far as accuracy is concerned the peroxide bomb method is superior or at least equal to the oxygen bomb. As evidence of the truth of this contention and the lack of agreement between three series of determinations made with the latter instrument by reputable laboratories on three oils, C. E. Waters (U. S. Bureau of Standards Tech. Paper 177) presents these data:

	Per Cent Sulphur
Mexican oil	1.52 to 1.90
Red oil	0.39 to 0.53
Vulcanized oil	0.89 to 1.22

He also states: "One laboratory alone reported five determinations on the red oil which ranged from 0.42 to 0.53 per cent, while eight results for the vulcanized oil varied from 0.89 to 1.19 per cent." There are differences of 20 to 27 per cent between the above results for the same oil. Differences between results reported in my paper seldom exceed 1 or 2 per cent. Since accuracy is the chief consideration in such research, there is no occasion for criticism because of the time element.

But let the question of accuracy and expense be neglected for a moment and only the factor of time be considered. In spite of Mr. Matthews' opinion to the contrary, the peroxide fusion method does not require more time and energy than the oxygen bomb method. It is at least as rapid as if not more rapid than the latter, and is less awkward. The peroxide bomb can be charged, closed, ignited, cooled and the contents removed with greater speed and ease than can the oxygen bomb. From here on the operations are practically identical in each case. If the oxygen bomb is equipped with a lead gasket, an additional quarter to half an hour

will be required to convert any lead sulphate, which might have been formed, to soluble sulphate. Where then does the saving of time come in through the use of the oxygen bomb? Since it is more expensive than the peroxide bomb and the results it gives are no more accurate than the peroxide bomb, I fail to recognize Mr. Matthews' suggestion as being either useful or illuminating.

Multiple Effect Evaporation

To the Editor of Chemical & Metallurgical Engineering

SIR:—On pages 110 to 115 of your number of July 20, 1921, appeared an article by Burton Dunglinson, entitled "Multiple Effect Evaporation." There are certain statements in this article which Mr. Dunglinson apparently gives without careful study or knowledge of the subject, and we would therefore ask you kindly to make the following corrections:

No Kestner evaporator up to 12,000 sq.ft. heating surface per body built in this country or to our knowledge in Europe has ever developed any "mechanical difficulties such as sagging of the tube due to its weight and consequent strain of the top tube plate with the result that leaks will develop."

The extremely large time of contact in the 20-ft. or rather 23-ft. Kestner tube does not exceed one-half the time the liquid is in contact with the Multiplex tube.

The average scouring effect produced in the Kestner tube due to the velocities is at least four times greater than that in the Multiplex tube.

The limiting height of the Kestner evaporator is the same as that of the Multiplex—namely, the height of a barometric condenser.

The floor space required for Kestners of such small sizes as the superimposed Multiplex is adapted to depends upon the space required for the auxiliaries, and in a Kestner installation is, therefore, no greater than in a similar sized Multiplex. In the larger sizes the Kestner evaporator requires less floor space than does the Multiplex, owing to the necessarily larger diameter steam belts in the shorter tube Multiplex body.

In fact, not one of the claims of superiority advanced for the Multiplex as an improvement in the art, but is equaled or surpassed by the older Kestner type.

KESTNER EVAPORATOR CO.,

Philadelphia, Pa.

RALPH MELLOR, President.

More on the Tellurides and Selenides

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring further to the subject of selenides and tellurides, concerning which I published a short note in your issue of Aug. 17, the sodium and potassium compounds are also interesting.

I first ran into these in an ill-advised attempt to produce metallic tellurium by direct reduction of the oxide, using sodium carbonate as a flux. The result was sodium telluride. The compound gives a beautiful solution if kept away from air, the color being very like that of potassium permanganate. Both the selenide and telluride decompose very readily from the oxygen of the air setting free metallic tellurium and metallic selenium with formation of sodium hydroxide. I believe that this reaction was made the basis by A. E. Knorr of a process for the recovery of these metals.

New York City.

DONALD M. LIDDELL.

Electric Furnaces for Silver, Gold and Metals of Low Melting Point

Points to Be Considered in the Electric Melting of Silver, Gold and Metals of Low Pouring Temperature and Their Alloys — Selection of Appropriate Furnaces — Results Obtained

By JONAS HERLENIUS

FOR many reasons the use of electric furnaces has lately been widely extended and will eventually include every industry, as soon as electric current is available at a reasonable price. Practically every known method of generating heat electrically has been utilized in the electric furnace art and it should therefore seem possible to select the proper furnace suitable for a particular purpose. The choice of furnace, however, requires a study of all the details connected with each individual melting problem in order to decide upon the type that will, as much as possible, answer all requirements.

UNDEVELOPED FIELD FOR ELECTRIC FURNACES

For the refining of steel and the melting of copper, nickel, aluminum, brass and bronze the electric furnace is now in use so extensively that the prospective user has a large field for practical investigation. Furthermore, there is ample literature available covering operating conditions, together with accurate figures on the results obtained. However, in the melting of some other metals, notably silver, gold, lead, zinc and tin, the electric furnace is in only limited use and for certain reasons its introduction is progressing very slowly. It should be only a question of time, nevertheless, until the merits of using electric furnaces for these metals will also be fully recognized, as it requires a type of work where the electric process is distinctly adaptable. Secrecy and limited use are the contributing reasons why so very little as yet has been published concerning the results obtained and other operating data from furnaces melting these metals. It must also be borne in mind that the part of this article dealing with the possibilities of electric furnaces in this new field is based on conclusions drawn from theoretical calculations or from the comparison of analogous conditions which occur during the melting of other metals.

ADVANTAGES IN THE USE OF ELECTRIC FURNACES

The electric furnace has the following main advantages over fuel-heated furnaces:

1. A more perfect temperature control.
2. Less loss by oxidation due to a neutral or reducing atmosphere.
3. A higher efficiency.

These three points are of such importance that it may safely be expected that any heating problem will ultimately be handled electrically when adequate furnace types have been developed. The prevailing high price of current in many districts, however, has greatly hampered the introduction of electric furnaces, mainly because the prospective user fails to understand that an eventual increase of his fuel cost will generally be

fully offset by a better quality of the product and by a higher efficiency of the melting equipment.

According to the method of heat generation, electric furnaces may be divided into the following main classifications:

1. Direct arcing furnaces, where the heat is generated in arcs between electrodes and the material charged, using it as a part of the circuit.

2. Free-burning arc furnaces, where the heat is generated independently of the charge, in arcs drawn between the tips of electrodes located above the metal.

3. Carbon resistor furnaces having special heating units located along the sides of the hearth, from which the heat is radiated to the charge, either directly or reverberated.

4. Induction furnaces, where the heat is generated in the metal itself by induction from primary coils suitably located; the furnace being constructed so that the metal charge forms a secondary closed circuit.

5. High-frequency induction furnaces, where the heat is generated in the metal charge or its container by eddy currents induced by current coils surrounding the crucible.

6. Wire-resistance furnaces, having special heating units in the form of wire coils located outside of the crucible containing the metal, from which the heat is conducted through the crucible wall.

The first class—i.e., direct arcing furnaces—which have found such extensive use in the melting and refining of steel, are not suitable for metals with low melting points. An excessive loss by volatilization is inevitable on account of the high temperature developed by the arcs in direct contact with the charge. This group of furnaces for that reason will not be considered here, while all the other furnace types will show important applications.

POINTS TO BE CONSIDERED IN THE MELTING OF SILVER

Silver has a melting point of about 1,760 deg. F. (about 960 deg. C.), has no low volatile oxide and can therefore be exposed to the air even at high temperatures without any danger of loss through oxidation. Silver, however, in the molten stage has the property of absorbing gases, especially oxygen, to a large extent. These gases are partly liberated on cooling, but partly retained in solid solution, giving rise to brittleness rendering the metal unfit for rolling. It is therefore necessary to exclude all air draught to avoid agitation of the metal, and to maintain a slightly reducing atmosphere in any furnace used for silver melting.

The boiling point of silver is about 3,550 deg. F. (about 1,950 deg. C.); some volatilization is supposed to occur at about its melting temperature. The loss

by volatilization is, however, very small as long as the liquid metal is not superheated to any great extent, but electric arcs close to or in direct contact with the metal are out of the question.

The pouring temperature of sterling or fine silver should be from 2,360 to 2,380 deg. F. (about 1,295 to 1,305 deg. C.), and if possible further superheating should be avoided. In pouring at a higher or lower temperature the metal is apt to crystallize coarsely upon solidifying, making it extremely brittle. An accurate temperature control in the furnace is therefore highly desirable in order properly to regulate the pouring temperature.

Any sudden chill in handling the molten metal, as for instance an excessive loss of time in transporting it from the furnace to the molds, will cause brittleness. For this reason lip-tilting type furnaces will best answer the purpose and usually specially designed pivoted pouring spoons are attached directly underneath the spout. The molds are located in front of this spoon to permit direct pouring, and care should be taken to preheat the spoon to incandescent heat and have it closed by a suitable cover.

Another important feature in silver melting is to prevent as much as possible the absorption of the metal in the lining. If crucibles are not used, the bottom should be tamped in with utmost care, using gannister or a suitable mixture of carborundum and fireclay. The rest of the furnace should be lined with either silica or a good grade of firebrick.

To summarize what is stated above, the following features are essential for a furnace to be employed in the melting of silver:

1. The furnace should produce enough heat in order that a sufficiently high pouring temperature may easily be reached and a quick melting down accomplished.
2. A proper application of the heat developed in the furnace must be provided for to avoid excessive local superheating and consequent loss by volatilization.
3. An efficient temperature control of the furnace is essential in order that the charge may be poured at the proper temperature and thereby avoid brittleness of the metal.
4. The furnace must be tight so as to exclude any air draught.
5. A suitable working door should be provided to allow for the introduction of slag-building material and to be able to work or stir the metal if necessary.
6. The furnace should be of the tilting type, preferably lip-tilted, to assure quick and efficient pouring.

VARIOUS TYPES OF FURNACES USED FOR MELTING SILVER

The Rennerfelt electric furnace, which is of the free-burning arc type, has been employed extensively for melting silver both in this country and abroad and seems to be especially adaptable for this purpose.

At the U. S. Mint in Philadelphia a 1,000-lb. capacity furnace operated continuously for several months, remelting 3,142,000 lb. of silver dollars into bullion. This furnace was taking off about twenty-two heats per twenty-four hours, with an average power consumption of 177 kw.-hr. per net ton. The total loss amounted to 0.75 oz. per 1,000 oz. and was due partly to volatilization, but mainly to absorption of metal by the lining, which later was recovered. The net loss after deducting the recovery was approximately 0.20 oz. per 1,000 oz. The actual melting time for a 1,000-lb. heat was fifty minutes.

FIG. 1. RENNERFELT ELECTRIC FURNACE INSTALLATION AT U. S. MINT, PHILADELPHIA, PA.

This furnace has a 150-kva., 40 deg. C. transformer bank, and is equipped with a two-electrode General Electric automatic electrode control. It is of the lip-tilting type and is tilted by means of a small 1½-hp. electric motor.

At another plant a 500-lb. 100-kva. Rennerfelt furnace is in operation on sterling and fine silver. This furnace is turning out about one heat per hour, with an actual power consumption of 250 kw.-hr. per net ton and an additional 80 kw.-hr. for preheating the furnace in the morning. The melting loss is practically negligible and amounts to only 4 oz. per heat of 5,000 troy ounces.

In practice the Rennerfelt furnace is preheated to at least a light yellow incandescent heat before charging the silver. After the metal is melted some powdered charcoal is generally scattered all over the bath and a slightly reducing atmosphere is maintained in the furnace. Too much charcoal, however, has been found injurious. With the metal there is often charged a small piece of wrought iron, which in practice seems to have very important advantages. The iron serves as a heat equalizer and furthermore will absorb to a great extent the oxygen present in the liquid silver.

Usually no slag building material is required except when it is necessary to remove zinc when the metal is slightly contaminated by german silver. An aluminum silicate slag is then built up of fireclay, which will bind the zinc as ZnO, although part of the metal will be eliminated in volatilization during melting down.

In order to ascertain the pouring temperature, spoon tests are generally taken from the furnace and poured into water. If the metal sticks to the spoon, it is far too cold, and a sufficient temperature is not reached until the silver granulates in the water and the spoon empties clean.

The variation in operating results with the Rennerfelt furnaces referred to is due to difference in practice and capacity and to the quality of the metal melted. The silver dollars are only remelted into bullion and the pouring temperature is therefore considerably lower than is otherwise required; this accounts for the lower power consumption.

In the furnace melting sterling and fine silver utmost care must be exercised in order to obtain sound castings and to make the metal fit for rolling and stamping.

This necessitates a considerably higher pouring temperature.

Only one carbon resistor furnace has been installed for the melting of silver—i.e., a Baily furnace at the William A. Rogers Co., Ltd., in Niagara Falls, N. Y. This is a pit type crucible furnace, used for recovering the silver from the company's electrolytic process for plating. The furnace is rated 30 kw. and accommodates two crucibles holding approximately 500 oz. each. These crucibles are lifted out for pouring; the metal is cast into anodes.

This Baily furnace has been in operation since 1914 and has given very satisfactory results in comparison with the oil furnace previously used. A great improvement was obtained especially in uniform heating and temperature control, which made it possible to pour the silver at a lower temperature and still obtain a more homogeneous metal. A slow, soaking, well-distributed heat and an accurate temperature control are very important advantages of the Baily furnace, which account for its great success in various metallurgical fields.

The pouring temperature of the metal melted at the Rogers company is estimated to be about 2,200 deg. F., although no pyrometer is used. This temperature is sufficiently high for a fluid metal when no complicated castings are poured or when the silver does not have to be rolled. Eight heats per day of 1,000 oz. each were poured with practically no loss. The average time for charging, pouring and melting of one heat was about one hour and seven minutes.

The power consumption with this furnace, however, was very high in comparison with other furnaces herein described. This, of course, is due to the fact that the metal is heated indirectly in crucibles.

It is a question whether it would not be more practical, especially in larger scale production, to melt the silver in the Baily furnace directly on the hearth instead of in crucibles. The excellent results obtained with free-burning arc furnaces in silver melting tend

to indicate that it ought to be feasible, even if the metal loss increased slightly.

Other carbon resistor furnaces, for instance the General Electric and the electric reverberatory types, will surely melt silver commercially either directly on the hearth or in crucibles similar to the Baily type used by the Rogers company. It is a fact, however, that the efficiency of all furnaces built on the principle of radiated resistor heat will be considerably less than for direct arcing types. Whether the employment of crucibles will compare favorably with open-hearth melting, due to lower metal loss and improved quality of the castings, can be determined only after further trials on a larger scale.

The ordinary horizontal ring induction furnace is not suitable for silver melting, because of "pinch" troubles due to the high electrical conductivity of the metal. Even the vertical ring induction furnace—for example, the Ajax-Wyatt—although used extensively in brass foundries, has not proved to be a successful type for silver melting. It is true that in this furnace the hydrostatic head of the molten metal will oppose the "pinch" force, but silver has so high an electrical conductivity that the efficiency of the furnace is considerably decreased. All induction furnaces, furthermore, require continuous operation or a liquid charge for starting, which naturally is a distinct objection in the handling of any precious metal, since the silver melting plants usually operate on but one shift.

HIGH-FREQUENCY FURNACES

The only high-frequency induction furnace on the market is the Ajax-Northrup type, which is manufactured in sizes up to 60 kw. power rating. Four of these furnaces are in operation at the U. S. Mint in Philadelphia for coinage silver and one at the plant of Handy & Harmon in Bridgeport, Conn., for sterling silver. The results obtained have been very gratifying. For this reason its operating conditions will be described in detail.

As stated above, silver has too high electrical conductivity to be melted with any satisfactory efficiency by direct induction. In order to overcome this obstacle, the Ajax-Northrup furnace is equipped with a crucible of molded carbon or graphite to replace or to fit into the crucible of non-conducting refractory material usually supplied. The heat is thus generated in the walls of this carbon crucible and transmitted to the metal contained by conduction or radiation.

The furnaces installed at the U. S. Mint in Philadelphia, Pa., are stationary, single-phase units, specially constructed to answer local conditions and to change the existing practice as little as possible. Two of these furnaces have been in operation for over one year on fine silver and gold for rolling and stamping. They have a power rating of 8 kw. each and hold two small crucibles, which are lifted from the furnace and poured. The two other furnaces are rated 16 kw. and accommodate one crucible each, from which the silver is dipped or ladled out until about 200 oz. remain, which are removed by withdrawing the crucible and pouring it out. Recently either one of the larger furnaces is operated two-phase, using 32 kw. power input, which corresponds to the total power that was originally intended for both units. This has considerably increased the efficiency and the two furnaces are now run alternately twenty-four hours.

FIG. 2. RENNERFELT ELECTRIC ARC FURNACE, STANDARD 500-LB. TYPE

FIG. 3. BAILY PIT TYPE ELECTRIC CRUCIBLE FURNACE AT WM. A. ROGERS CO., NIAGARA FALLS, N. Y.

In a trial run with one of the larger furnaces at the U. S. Mint four charges, constituting 13,490 oz., were melted in seven hours' time, with a power consumption of 156.5 kw.-hr. This is equal to 5.9 lb. per kw.-hr., or 340 kw.-hr. per net ton. The average load was $12\frac{1}{2}$ kw. per phase, or a total of 25 kw., and the metal loss was almost negligible.

The furnace at Handy & Harmon's is lip-tilted and pours directly into the molds without intermediate ladles or pouring spoons. It is a three-phase installation, which absorbs 60 kw. from the supply line, 30 to 40 per cent of which is lost in the high-frequency converter. This makes an actual power rating of the furnace crucible of about 40 kw.

The furnace has a capacity of about 600 lb. of silver per melt. One day's operation shows a production of 36,558.50 oz. of sterling silver melted in eight hours and fifteen minutes, including preheating, and uses about 317 kw.-hr. This makes an average of 7.95 lb. of silver per kw.-hr. for the entire time consumed, or a power consumption of approximately 252 kw.-hr. per net ton.

The Ajax-Northrup furnace consequently shows remarkable efficiency in the melting of silver and in case the mechanical defects are overcome, this furnace should answer most of the requirements for silver melting on a smaller scale. The life of the conducting crucible will have to be established from further trials and there still remains the question as to whether this part of the furnace will meet all requirements in general commercial operation. A distinct advantage of this high-frequency type is that in melting in a closed crucible the metal is prevented practically from absorbing any gases. On the other hand, the removal of zinc, in case the silver is contaminated by german silver, is not possible. The practice of inserting a piece of iron into the metal bath of this furnace would materially disturb the induction. There is less need for a deoxidizer, however, and no heat equalizer is required in a furnace where the heat distribution is so nearly perfect.

Wire-resistance furnaces do not produce sufficient heat to melt silver and are consequently not applicable.

POINTS TO BE CONSIDERED IN THE MELTING OF GOLD

Gold is always alloyed to a certain extent with some other metal, especially copper, silver or platinum. It has a melting point of about 1,950 deg. F. (about 1,065 deg. C.), begins to volatilize around 2,010 deg. F.

(about 1,100 deg. C.) and volatilizes four times as fast at 2,280 deg. F. (about 1,250 deg. C.). The pouring temperature should therefore be slightly above its melting point and excessive superheating must be carefully avoided in order to prevent any loss by volatilization of this precious metal.

Gold should only be melted in crucibles and the main requirements of a suitable furnace are an accurate temperature control and a uniform heat distribution. Gold is so expensive that low loss handling is paramount, while the efficiency of the melting equipment ranks next in importance, but does not have the same bearing from the standpoint of economy.

Arc furnaces are not suitable for heating crucibles, on account of insufficient temperature control and subsequent danger of superheating. Carbon resistor furnaces may be applicable and especially the previously described Baily pit furnace used at the William A. Rogers Co., Ltd. This type has a slow, soaking heat and possesses excellent means for an accurate temperature control.

Other furnaces belonging to the same group, especially the General Electric and the electric reverberatory types, could probably be adapted if constructed for the purpose. Thus far, however, no furnaces of these types have been employed for melting this metal.

Gold has too high electrical conductivity to be melted by direct induction. Such furnaces are consequently not suitable, with the exception of the Ajax-Northrup, where a conductive crucible is used as described under silver melting. Some small furnaces of this type have been installed for gold melting, using a graphite crucible, and the performances have been very satisfactory. In a 6-in. crucible with a net volume of 53 cu.in. 37 lb. of gold can be melted in eight minutes at a rate of 14 lb. per kw.-hr. consumed. The crucible is coated with a special refractory material which will cohere to the graphite and withstand a high temperature in order to prevent the crucible from being oxidized by the air.¹

If the gold is alloyed with platinum, a metal which has a very high resistivity, the resultant electrical

¹See CHEM. & MET. ENG., June 22, 1921. Footnote on p. 1099.

FIG. 4. STANDARD BAILY ELECTRIC FURNACE AT THE LUMEN BEARING CO., BUFFALO, N. Y.

conductivity may be decreased sufficiently so that the alloy can be melted by direct induction in a clay or magnesite crucible. This is of great importance in the melting of gold-platinum alloys, due to the fact that any contamination by carbon is to be avoided and a more homogeneous metal can be produced, due to the stirring action caused by the currents induced in the bath.

In a test recently carried out 50 troy ounces of an alloy containing 85 per cent fine gold and 15 per cent pure platinum were melted in a No. 5 clay crucible which was washed inside with electrically sintered magnesia. In six minutes the charge was melted and considered sufficiently fluid for pouring. The ingot cast was rolled out and found to be free from platinum streaks, which frequently appear when using gas- or oil-fired crucibles.

There are many reasons why the high-frequency induction furnace may be considered particularly well adapted for melting gold and platinum. It enables the melting of very small quantities of metal with comparatively high efficiency. The furnace also possesses an accurate temperature control and a uniform, well-distributed heat. Furthermore, the stirring action which is an inherent feature with direct induction furnaces is an important advantage in alloying gold and platinum.

POINTS TO BE CONSIDERED IN THE MELTING OF ZINC, TIN AND LEAD

When melting metals of very low pouring temperature, only such furnaces should be employed as possess either suitable means for accurate low-temperature control or where the source of heat is limited to a certain temperature equilibrium. This concerns practically all metals or alloys that melt below 1,000 deg. F. (540 deg. C.) and include zinc, tin and lead and their alloys

FIG. 5. MELTING CHART OF A LEAD ALLOY HAVING A MELTING POINT OF ABOUT 370 DEG. C.

and certain other important alloys of these metals with copper, bismuth, antimony and cadmium. It is feasible to melt any of these metals or alloys electrically if adequate furnace types are employed, and a very rapid development of electric melting in this new field of metallurgy may be expected in the near future. This

is a very comprehensive subject, however, and the limits of this article preclude any detailed account.

All arc furnaces produce too much heat and are therefore not suitable for metals of low melting point.

Resistance radiating furnaces have a close temperature control and should therefore be well suited under certain conditions. For large-scale production, demanding furnaces in tonnage capacities, this type is so far the only one available. One Baily furnace is in operation at the Lumen Bearing Co., in Buffalo, N. Y., melting "Lumen" metal, which is an alloy of 85 per cent Zn, 10 per cent Cu and 5 per cent Al. It is a 105-kw. tilting type furnace of 1,000-lb. capacity producing about one heat per hour, with a power consumption of from 200 to 240 kw.-hr. per net ton. The metal is poured at a temperature of about 1,300 deg. F. (about 705 deg. C.), and the metal loss varies between 2½ and 3½ per cent.

As all these metals have rather low electrical conductivity, it should be possible to melt with direct induction, in case 24-hr. operation can be established and the composition of the alloy is not changed too frequently. The high thermal efficiency and the circulation in the metal bath are features of great advantage with this type of furnace.

The Ajax-Northrup high-frequency induction furnace employs an iron crucible as a container for lower melting metals and alloys. The heat is developed in the iron by induction, which can be done with high efficiency and almost perfect temperature control. Using a 10-in. crucible, 25 lb. of zinc can be melted in six minutes at a rate of 13 lb. per kw.-hr.; 25 lb. of tin and 39 lb. of lead are melted in two and one-half minutes at the rate of 30 and 50 lb. per kw.-hr. respectively.

Wire-resistance furnaces are very well qualified for any kind of low-temperature work, because the temperature is under perfect control by changing the connection of a number of the heating elements surrounding the crucible. The heat input is furthermore limited so that excessive superheating is rendered impossible, and after the desired temperature is reached by adjusting the power input this temperature is maintained by a constant heat supply. The furnace works slowly but with comparatively high efficiency and is particularly well adapted when it is desired to keep a metal liquid at a constant temperature for a long time. This principle of electric heating should therefore be used to advantage in heating soldering pots, lead baths for annealing purposes, melting stereotype metal, etc. A series of trial runs with a small furnace of this type have been submitted by Hamilton & Hansell, Inc. The variation in temperatures in one of these runs is represented by the curve shown (Fig. 5) and refers to a lead alloy having a melting point of about 700 deg. F. (about 370 deg. C.).

The furnace was preheated empty to about 840 deg. F. (about 450 deg. C.) in twenty minutes, using about 2½ kw.-hr. and afterward charged with 176 lb. of lead. The metal was melted in twenty-five minutes, superheated in an additional twenty-five minutes and poured at about 960 deg. F. (about 515 deg. C.). The average power input was about 55 volt, 125 amp. d.c. or 6.9 kw. The total consumption of power was 6½ kw.-hr., of which 4 kw.-hr. was actually consumed for melting. This is equal to 27 lb. of metal per kw.-hr. covering all the time used, or 44 lb. per kw.-hr. excluding the preheating.

Studies in Evaporator Design—V

Experimental Data for Horizontal Tube Evaporator Showing Relation Between Hydrostatic Head, Temperature Drop and Heat Transmission—Ratio of Corrected Coefficients for Two Different Temperature Drops Is Constant for All Levels*

BY W. L. BADGER

THIS paper presents two curves showing the relation between hydrostatic head and heat transmission in a horizontal tube evaporator. These two curves were determined at the same boiling point, but with a different steam temperature for each curve; thereby furnishing means for determining the relation between hydrostatic head, temperature drop and heat transmission.

So far as the writer has been able to determine, no systematic experimental work has been done on horizontal tube evaporators. There are scattered tests of horizontal tube evaporators available, but they are all reports of isolated tests on evaporators in actual plant operation, and are therefore not available for systematic study. The previous literature regarding the effect of hydrostatic head on heat transmission and regarding the effect of temperature drop on heat transmission has been discussed elsewhere.¹

DESCRIPTION OF APPARATUS AND METHOD OF PROCEDURE

These tests were run in the horizontal tube evaporator of the Evaporator Experiment Station at the University of Michigan, which has been described in detail.² Briefly, the evaporator body is 25 $\frac{3}{4}$ in. wide inside and, in these tests, it was 8 ft. high inside. It was equipped with 156 steel tubes $\frac{7}{8}$ in. in outside diameter by $\frac{1}{8}$ in. wall, with an effective length of 46 $\frac{1}{4}$ in., making a net heating surface on the wet side of 0.883 sq.ft. per tube. The total heating surface was therefore 137.75 sq.ft., or 12.795 sq.m. The arrangement of the tubes is shown in Fig. 1. In calculating the heating surface, no allowance was made for the tube sheets, which are of cast iron, 1 $\frac{1}{4}$ in. thick. The tubes are secured in these tube sheets by the standard Swenson tube packing plate (see Fig. 2). When tubes of this size with their centers 1 $\frac{5}{8}$ in. apart are so secured, the pressure of the packing plate results in a spreading of the gaskets until they unite in a practically continuous sheet of rubber, perhaps $\frac{1}{8}$ in. thick. The packing plates themselves are 1 in. thick and form a continuous sheet. This combination of 2 $\frac{1}{4}$ in. of cast iron and $\frac{1}{8}$ in. of rubber offers so much resistance to heat transmission as compared to the $\frac{1}{8}$ in. of steel in the tubes proper that it was considered reasonable to omit the tube sheets entirely. In this experimental evaporator the tube sheets are very large, and consequently in this set of experiments a large part of the tube sheet was blanked off. In blanking off holes not in use, the same gaskets and packing plates were used

as were used in securing tubes, so that there is no need to consider the upper part of the tube sheets as being a part of the heating surface.

Air was vented from the top of the front steam chest into the vapor space; and from the bottom of the front steam chest through the condensate receiver and back to the vapor space. Condensed water was taken from the front steam chest only.

When the evaporator was boiling smoothly and conditions seemed uniform, at a signal from the recorder the level of condensate in the receiver was marked, and readings of all temperatures and pressures were begun at once. Readings were taken every two minutes until a sufficient amount of condensed water had accumulated; or in the case of runs at high ratings, until at least ten or twelve sets of readings had been taken. At a signal from the recorder the time was again noted and the amount of condensed water again marked. The evaporator was connected to another receiver, and as soon as conditions had become uniform the next run

FIG. 1. ARRANGEMENT OF TUBES IN EXPERIMENTAL EVAPORATOR

was started. This usually involved a lapse of five to seven minutes, during which time the evaporator was kept boiling and the conditions kept as constant as possible. In series T there was but one break. Runs 128A, 151B and 259 were made without a shutdown, and then runs 129A, 152B and 260 were also made consecutively. In series U runs 130A-I, -II and -III were made consecutively. There was then a break until the next day, when runs 153B, 154B, 261 and 262 were made consecutively. There was another break, and runs 155B, 156B and 131A were made.

METHODS OF MEASUREMENT AND ACCURACY OF RESULTS

Time was measured with an ordinary watch, and it is probably correct to within ± 2 seconds. The vacuum was controlled by the automatic vacuum regulator described in a previous paper³ and usually did not vary over ± 2 mm. during a test. Therefore the probable error of the average for a test is very small (less than ± 0.1 mm.). Temperatures of the vapor space were not read systematically, but when read they came so near to the temperature calculated from the vacuum as to indicate no constant error in the manometer

FIG. 2. TUBE PACKING PLATE SHOWING METHOD OF SECURING TUBES

greater than ± 1 mm. (or ± 0.13 deg. C. at 60 deg.). In a previous paper⁴ there is a discussion of the reasons for preferring temperature calculated from vacuum as the temperature of the boiling liquid rather than temperature determined by a thermometer inserted into the machine. It should be noted that in calculating on the basis of the temperature corresponding to the vacuum the results are in terms of apparent temperature drop and are therefore apparent coefficients.

Steam pressures were measured by mercury manometers attached directly to the steam chests. Long ex-

eters on an instrument board. A special brass stuffing box was screwed into a tapped hole in the steam chest covers. Glass manometer tubes were made with the end of one arm bent horizontal to enter this stuffing box. Water slowly accumulated in the steam side, but it was measured at each reading and allowed for in the calculations. The average of the manometer readings is probably accurate to less than 1 mm. This is equivalent to ± 0.04 deg. on the saturation temperature for series T, and ± 0.05 deg. for series U.

Steam temperatures, because of the accessibility of the steam chests of a horizontal tube evaporator, can be ascertained much more satisfactorily than in the vertical type evaporator. Four calibrated thermometers were inserted in each steam chest, distributed over the part opposite the ends of the tubes in use. The averages of these thermometer readings are given in Tables I and II. (The "back" steam chest is the one in which the steam enters.) The probable error of the average temperature in the back steam chest was about ± 0.3 deg. Condensate temperature was measured in the condensate line about 3 ft. from the steam chest. The error of this reading may have been ± 0.2 deg.

HEAT AVAILABLE

It will be seen from the data of these tables that there was considerable superheat in all the runs. This is because high-pressure steam was used and throttled at the evaporator. The heat transmitted through the heating surface per kg. of steam condensed is, therefore: (1) Heat given up as superheat in cooling to saturation temperature. (2) Latent heat of condensation. (3) Sensible heat given up by condensed water in cooling from saturation temperature to the temperature at which it left the evaporator. (4) Heat given up in cooling from the temperature of the back steam chest to the temperature of the front steam chest, by steam bled through vents or condensed by radiation in condensate lines and condensate receivers. Of these, No. 4 may be omitted as too small to consider. The other items may be readily calculated. In this respect the work on the horizontal tube evaporator is more definite than on the vertical tube evaporator. The superheat may be in error by ± 0.15 cal.; the latent

perience with metal piping (both ordinary iron pipe and fittings and seamless copper tubing) has led us to distrust manometers for steam which are any great distance from the point at which the pressure is to be measured. We therefore abandoned the idea of manom-

³CHEM. & MET. ENG., vol. 23, No. 4, p. 161, July 28, 1920.

⁴CHEM. & MET. ENG., vol. 23, No. 6, p. 241, Aug. 11, 1920.

heat by ± 0.03 cal.; and the sensible heat by ± 0.2 cal. Since the total heat given up per kg. of steam condensed was about 550 cal., the greatest probable error would be ± 0.4 cal., or 0.08 per cent.

It is interesting to note that the temperature drop from the back steam chest to the front steam chest (calculated from pressure) was of the order of a few hundredths of a degree. In most cases the drop is toward the front steam chest, as would be expected. In series T, the pressure drop in 151B-II is evidently in error. Omitting this, there is no difference between the two steam chests over 0.18 deg. in either series. The average difference is $+0.01$ deg. in series T and $+0.02$ deg. in series U.

CALCULATION OF APPARENT TEMPERATURE DROP

In calculating the apparent temperature drop there are complications due to the presence of superheat. In order to handle the calculations it will be assumed that the processes are as follows: First the steam is cooled to the saturation temperature, giving up its superheat. Next it is condensed to a liquid at a temperature corresponding to the mean of the pressures in the front and

FIG. 3. TEMPERATURE GRADIENT IN THE HORIZONTAL TUBE EVAPORATOR

- t_w = temperature of boiling liquid.
 t_b = temperature of superheated steam entering tubes from back steam chest.
 t_s = temperature of saturated steam in tubes.
 t_c = temperature of condensed water.

back steam chests. Finally, the condensate is cooled from this temperature to the temperature at which it leaves the evaporator. Under these assumptions the following formulation holds: (See Fig. 3.)

- t_b = temperature of back steam chest from thermometers.
 t_f = temperature of front steam chest from thermometer.
 t_s = temperature of saturated steam corresponding to mean of the pressures of front and back steam chests.

t_c = temperature of condensed water.

t_w = temperature corresponding to vacuum.

θ_s = mean temperature difference during transfer of superheat.

θ_l = mean temperature difference during transfer of latent heat.

θ_c = mean temperature difference during transfer of sensible heat of condensate.

H_s = Heat as superheat in cal. per kg.

H_l = latent heat in calories per kg.

H_c = sensible heat recovered from 1 kg. of condensate.

θ_m = mean apparent temperature drop.

$$\text{Then } \theta_s = \frac{(t_b - t_w) + (t_s - t_w)}{2} \quad (1)$$

$$\theta_l = t_s - t_w \quad (2)$$

$$\theta_c = \frac{(t_s - t_w) + t_c - t_w}{2} \quad (3)$$

$$\theta_m = \frac{\theta_s H_s + \theta_l H_l + \theta_c H_c}{H_s + H_l + H_c} \quad (4)$$

In equations 1 and 3 the arithmetical mean has been

used instead of the logarithmic mean. This is because H_s and H_c are so small that the error so made in θ_s and θ_c is without significance in the final result.

The above method of calculation was applied to a number of runs. The results of a few, selected because they represent extremes, appear in Table III. As will be seen, H_s and H_c are so small in comparison with H_l that they are not significant. In view of the amount

$\theta_m - \theta_l$	+0.11	+0.05	+0.13	+0.19	+0.15	+0.08

of calculating saved, θ_l has been used in all the data of this paper instead of θ_m . The total heat available from 1 kg. of steam condensed was, however, determined by taking the sum of H_s , H_l and H_c . Hence the values used for θ may be in error by not over ± 0.2 deg. due to this method of calculation. As stated above, t_w has an error of ± 0.13 deg., and $t_s = 0.05$ deg. Therefore the final values for θ may have a maximum error of ± 0.4 deg. or ± 2.6 per cent, in series U and ± 1.6 per cent in series T.

In all cases temperatures were read to tenths of degrees and pressures to millimeters of mercury. In all calculations temperatures were carried to hundredths of degrees and pressures to tenths of millimeters. The final results were rounded off to the nearest whole number for the values of K and U . So far as the probable error of any of the determinations goes, the final result is probably accurate to 1 to 2 per cent. However, the possibility of systematic errors makes us doubtful whether we should assign a greater accuracy than ± 50 to any figures for K . Duplicates can be obtained closer than this.

RESULTS

The data for the two series are given in Table IV and are plotted in Fig. 4. From the data of these tables it would seem that in runs 131A, 155B and 156B, there was not enough venting from the front steam chest, so that some air accumulated at that point. In series T steam pressures throughout were above atmospheric pressure and therefore it was easy to keep the steam chests free of air.

EFFECT OF SUPERHEAT

The question on the effect of the presence of superheat is one which has been discussed many times in the literature. A few scattered tests are available to show the effect of superheat, but as a general thing they are not systematic and lead to contrary conclusions. In no case have tests been carried out where the total heat transmitted was entirely or even largely superheat.

FIG. 4. APPARENT AND CORRECTED HEAT TRANSMISSION COEFFICIENTS FOR TWO DIFFERENT TEMPERATURE DROPS (SERIES T AND U)

from superheated steam may be working at a rate which is relatively very low, but this part of the surface is too small to affect the results appreciably.

It will be noted that these statements are purely qualitative. For the present we prefer not to attempt to deal in numerical statements. By a rearrangement of the steam lines in the experiment station it is now

possible to operate the horizontal tube evaporator on steam of pressure low enough so that there is no appreciable superheat, even in the steam chest. By a comparison with the runs here reported we hope to confirm the above qualitative statements with quantitative data in the near future.

The data of Table IV are apparent heat transmission coefficients—that is, they are determined by dividing the total heat transmitted by the apparent temperature drop. They may be corrected for effect of hydrostatic head by the following method. (See Fig. 5.)

In addition to the nomenclature given above under

the calculation of temperature drop, the following are needed:

- p_v = absolute pressure in vapor space.
 p_h = hydrostatic head on bottom of heating surface.
 p'_h = hydrostatic head on top of heating surface.
 p_b = total pressure on bottom of heating surface.
 p_t = total pressure on top of heating surface.
 t_b = temperature corresponding to p_b .
 t_t = temperature corresponding to p_t .

FIG. 5. ILLUSTRATION OF METHOD OF CORRECTING HEAT TRANSMISSION COEFFICIENTS FOR EFFECT OF HYDROSTATIC HEAD

For those cases where the liquid is above the top of the heating surface we have the following:

- θ_1 = apparent temperature drop = $t_s - t_w$.
 $p_t = p_v + p'_h$.
 $p_b = p_v + p_h$.
 $\theta_2 = t_s - t_b$ = temperature drop at bottom of heating surface.
 $\theta_3 = t_s - t_t$ = temperature drop at top of heating surface.
 θ_{mh} = mean temperature drop corrected for effect of hydrostatic head = $\frac{\theta_3 + \theta_2}{2}$

For those cases where the liquor level is below the top of the heating surface the formulation becomes:

- $p'_h = 0$, hence $t_t = t_w$.
 $\theta_2 = t_s - t_b$ = temperature drop at bottom of heating surface.
 H_a = heating surface above liquor level.
 H_b = heating surface below liquor level.
 $\theta_4 = \frac{\theta_1 + \theta_2}{2}$ = mean temperature drop over submerged part of heating surface.
 $\theta_{mh} = \frac{H_a \theta_1 + H_b \theta_4}{H_a + H_b}$

There are certain errors made in the above corrections of which the writer is aware but which do not introduce enough error to be significant. In particular, the mean temperature drop is, of course, not the arithmetical mean of the temperature drops at top and bottom of heating surface, but is determined by some other function which involves the relation between the

series T, is at once evident; and some search was made for a quantitative relation. Table VI showing the ratios of the corrected values in the two series indicates at once a very useful relation—namely, that if the ratio of heat transmission coefficients for different temperature drops is determined for a given evaporator at any one liquor level, the same ratio may be used for other liquor levels with an accuracy far greater than that now involved in any other part of the design.

CONCLUSIONS

The following conclusions must for the present be considered as indicating tendencies only, and must be applied with caution to evaporators differing much in design from the one in which they are determined.

1. In horizontal tube evaporators the maximum capacity occurs when the tubes are from half to two-thirds submerged.
2. The maximum capacity is reached at levels nearer the top of the heating surface as the apparent temperature drop becomes smaller.
3. The maximum apparent heat transmission coefficient is 105 to 108 per cent of the heat transmission coefficient where the liquor level is at the top of the heating surface.
4. The ratio of corrected heat transmission coefficients for two different temperature drops is constant for all levels above the optimum.

All of the work reported in this paper was done with funds supplied by the Swenson Evaporator Co., to which the writer wishes to express his indebtedness for permission to publish the result.

Pronounced Benefits From Preliminary Impregnation of Pulpwood Chips*

Impregnating pulpwood chips with cooking liquor under pressure before the cooking action has commenced has been found decidedly advantageous in the soda and sulphate processes of pulping. The required pressure is obtained by pumping cooking liquor into the digester after it has been completely filled and closed. The amount of pressure necessary, duration of treatment and other factors vary with the type of cooking process, kind of chips used and quality of paper sought.

Laboratory cooks of treated chips on a 50-lb. scale showed greater uniformity of cooking, increased yields, reduced bleach consumption, increased concentration of the cooking liquor and reduced time for cooking.

Mill trials of the improved method on a 3-ton scale resulted in increased concentration of the cooking liquor, reduced time for cooking, a reduction of the steam required for cooking from 9,000 to 6,000 lb. per digester charge and an increase in the concentration of black liquor from the digester from 15 to 18 deg. Bé.

The saving in time required for cooking was estimated to be sufficient to offset the time required for impregnation. The saving in steam consumption made possible an increase of from 12 to 20 cooks per day from a 250-hp. steam boiler. The increase in the density of the cooking liquor was estimated to make possible an increase of 25 per cent in the output of the recovery house.

Nitric Acid With Sulphuric Acid Added to Prevent Corrosion Not Subject to Duty

The Supreme Court of the United States has upheld the judgment of the Court of Customs Appeals in the proceedings on protests of the Aetna Explosives Co. against assessments of duty on imported goods. (41 Sup. Ct. R. 513.)

The imported merchandise was nitric acid to which 20 per cent by weight and 5 per cent according to value of sulphuric acid had been added for the sole purpose of preventing corrosion of steel tank cars necessary for transportation of the nitric acid in large quantities. The court below found that the sulphuric acid was added solely for transportation purposes and that the result was not a product merchantable as such for use in the United States. Hence it held that no duty should have been demanded, and the Supreme Court affirms this decision.

In the 1913 tariff act, paragraph 387, including nitric and sulphuric acid in the free list, and paragraph 5, imposing a duty of 15 per cent ad valorem on all chemical and medicinal compounds, preparations and mixtures, nitric acid, to which sulphuric acid amounting to 20 per cent by weight and 5 per cent according to value has been added solely to prevent corrosion of the steel-carrying tank cars, is not subject to duty as a "preparation" or mixture.

The merchandise was not a commercial mixture contemplated by the statute. It was susceptible of no use other than as nitric acid, which must be treated again before use. The court said the mixing of this minimum amount of sulphuric acid should be treated as a means of and part of the shipment, and as an act as essential in the importation of nitric acid as would have been the proper packing of glassware or other goods designed for shipment by rail.

Cyanide Pond Owners Liable for Death of Live Stock

The case of Williams Estate Co. vs. Nevada Wonder Mining Co., 196 Pacific, 844, involves the liability of the mining company for loss of cattle from drinking cyanide solutions discharged from its mill, located at Wonder, Nev. It appears that the solutions flowed down a slope for a mile or so and there were collected in a pond. This pond was situated for the most part on mining ground owned by the mining company but extended over onto the public domain. These cyanide solutions are highly poisonous, but as they resemble water are attractive to cattle and other live stock. The mining company kept the pond fenced with barbed wire and posted notices warning owners of live stock of its dangerous contents. The company generally kept two men to impound these cyanide solutions, and on the day of the loss for which suit was brought the solutions broke through the levee of the pond and flowed outside the fence.

Plaintiff's cattle coming from the open range were attracted to the spot, drank the solutions and died.

A judgment was rendered for the loss of the cattle in the District Court and the Supreme Court of Nevada

has affirmed this decision. Nevada has no law requiring stockmen to keep their stock within inclosures, and they may lawfully permit such to roam at will and graze over the public ranges and also over unfenced land of private owners. In fact, a herder of horses or cattle upon public and other uninclosed lands is unknown to the stockmen in Nevada, says the court, and a mine owner creating a cyanide pond in proximity to and in open view of the public range, with knowledge of the poisonous nature of its contents and its attractions for cattle, is required to exercise reasonable care to prevent access to it by live stock.

Ordinarily one is not bound to keep his uninclosed premises in safe condition to avoid liability for injury to trespassing stock, but he is not permitted negligently to leave on his premises poisonous substances which will attract passing animals.

Nuisance in Storage Crude Petroleum

In an action brought by H. A. Lutes et al. against the Great Northern Refining Co., plaintiffs were awarded damages through defendant's erection and maintenance of an oil tank shipping rack in close proximity to their residence. It was charged that crude petroleum was being constantly pumped through the tank to the cars for shipment and that the gases and fumes escaping from the crude oil were so offensive, disagreeable and injurious as to constitute a nuisance and so as to make their residence uninhabitable. It was further alleged that because the oil was impregnated with gas and was highly flammable they were in constant danger of having their property destroyed by fire. (227 S.W., 795.)

The Court of Appeals of Kentucky reversed the Circuit Court's judgment for an error on the trial and a new trial was ordered. This court lays down the law that the storage of oil upon one's premises is not *per se* a nuisance. A lawful business cannot be a nuisance *per se*, but the character of the business, the manner in which it is conducted and its proximity to other buildings and the surrounding circumstances may be such as to create a nuisance. It is not every annoyance that will give a right of action to the complaining party. A nuisance is that which offends the olfactory nerves of an ordinary man, and not those of an individual with sensitive and delicate nostrils.

Further, the court says, every one who brings or stores oil on land must confine it securely in pipes, tanks or reservoirs, or at least not permit it to escape onto the land of another, whether by flowing over the surface or percolating through the soil, and if one does not, even though guilty of no negligence, he will be liable for whatever damage is suffered by the oil escaping. This is true, although the refining of oil is a perfectly legitimate business. Nor is the owner of property, injured by the operation of oil wells or works, confined to instances where the oil actually enters upon his premises, as he may recover because of noxious odors occasioned by their operation rendering his premises unhealthful or objectionable to live upon.

However, the court said, the question of prospective damage from fire should not have been submitted to the jury. It was too problematical. Ordinarily the mere anticipatory loss by fire because of the possibility that the tank might be struck by lightning or fired by a spark from a locomotive does not form a basis for a legal recovery. It might never happen; and if it did, and the owner was negligent, there would be a proper remedy.

Preliminary Summaries of 1919 Census of Manufactures

Tabulated Statistics for Chemicals, Drug Preparations, Natural Dyes and Extracts, Fertilizers, Gas, Leather, Paper and Wood Pulp, Petroleum Refining, Rubber Goods, Soap, Brass, Bronze and Copper Products, Pig Iron, Industrial Power and Fuel Consumption in Superpower Zone

PRELIMINARY statements of the general results of the 1919 census of manufactures with reference to a number of chemical and metallurgical industries have been issued by the Bureau of the Census. Comparative statistics for 1919 and 1914 are summarized in the following tables, figures for 1919 being subject to such change and correction as may be necessary from further examination of the original reports.

CHEMICAL INDUSTRY

The chemical industry is subdivided for establishments primarily engaged in the manufacture of (a) chemicals in general; (b) coal-tar chemicals; and (c) sulphuric, nitric, and mixed acids; and the figures are based upon returns from 811 establishments, with products valued at \$603,555,400. In addition chemical products were reported by 563 establishments primarily engaged in other lines of manufacture, to the value of \$91,087,600, making a total of 1,374 establishments and \$694,643,000 in value of products.

At the census of 1914 there were in the aggregate 754 establishments, with products valued at \$200,195,800, showing an increase of \$494,447,200 or 247 per cent.

(a) Includes synthetic preparations in 1919—4 establishments; value \$404,585; 1914—75 establishments; value, \$1,384,996.
 (b) Figures not available.

NATURAL DYES AND EXTRACTS

The total production of natural dyestuffs in 1919 as reported by all manufacturing establishments was valued at \$4,689,000, as compared with \$1,862,200 in 1914, and the total production of tanning materials was

valued at \$32,625,300 in 1919, as compared with a production of \$7,898,700 in 1914. In addition the establishments reported the manufacture of mordants to the value of \$1,218,700, assistants valued at \$2,845,300 and sizes to the amount of \$11,580,500.

Grease (soap stock, etc.)			\$2,162,200	\$1,209,300
All other products			\$6,947,600	\$8,140,200

(a) Includes 100 cottonseed oil mills, 51 slaughtering and meat packing plants, and 68 establishments in other industries producing waste of fertilizing value.

GAS INDUSTRY

The figures are based on returns from 1,020 establishments, with products for the year valued at \$328,851,000. At the census of 1914 there were 1,244 establishments with products valued at \$217,920,000, an increase of \$111,931,000, or 50.9 per cent. The decrease in number of establishments is chiefly in the small town and village plants of the acetylene or gasoline groups, there being but 37 acetylene and 22 gasoline (cold process) plants in 1919 as compared with 125 and 112 respectively in 1914.

The total production of gas for sale in 1919 was 307,913,000,000 cu.ft., valued at \$281,865,000, an average value of 91.5c. per thousand feet. In 1914 the production was 203,517,500,000 cu.ft., valued at \$172,748,000, or an average unit value of 84.9c. The increase in quantity was 104,395,500,000 cu.ft., or 51.3 per cent, and in value \$109,117,000 or 63.2 per cent.

* In addition six establishments in 1919 and five in 1914, primarily in other lines of manufacture, distributed gas through mains—1919—64,200 M.cu.ft.; value \$112,480; 1914—51,898 M.cu.ft.; value \$61,405.

† Not including forty establishments without mains, included in report for gas industry in 1914 (product compressed gas in cylinders—121,696 M.cu.ft., value \$2,317,600).

‡ Figures not available.

§ Includes benzene, benzine, gasoline, naphtha and calcium carbide.

GLASS INDUSTRY

The preliminary report for the glass industry during 1919 was published in CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, p. 1017, June 8, 1921.

LEATHER INDUSTRY

Reports were received from 681 establishments, having a total output valued at \$928,668,200. In 1914 there were 767 establishments with a total value of products amounting to \$367,201,700. Of the 681 establishments reported for 1919, 131 were located in Massachusetts, 94 in New York, 92 in Pennsylvania, 73 in New Jersey, 30 in Illinois, 28 in Michigan, 25 in Wisconsin, 24 in Ohio, 21 each in California and Virginia, 18 in Delaware, 17 in West Virginia, 11 in North Carolina, 10 each in Kentucky and Tennessee, 9 each in Indiana and Maine, 7 each in Connecticut, Maryland, Missouri and New Hampshire, 6 in Minnesota, 5 in Oregon, 3 each in Georgia and Texas, 2 each in North Dakota, Rhode Island, Vermont and Washington, and 1 each in

Alabama, Colorado, Louisiana, South Dakota and Wyoming.

COMPARATIVE SUMMARY FOR THE LEATHER INDUSTRY
1919 AND 1914

	1919	1914
Number of establishments	681	767
Value of products	\$928,668,200	\$367,201,700
Leather, value	\$848,038,500	\$341,796,400
Sole leather, sides	19,715,800	18,075,500

Case, bag, and strap leather, value	\$11,880,800	\$5,383,300
Skirting and collar leather, value	\$5,998,700	\$2,083,000
Bookbinders', value	\$3,463,800	\$1,362,700
Sold in rough, value	\$3,712,700	\$4,495,000
All other leather, value	\$46,508,600	\$15,956,600
Amount received for work done for others	\$51,913,800	\$12,270,900
All other products	\$28,715,900	\$13,134,400

PAPER AND WOOD PULP INDUSTRY

Returns were received from 713 establishments engaged in the industry in 1919, with products to the value of \$789,548,000. Of the total number, 481 establishments manufactured paper only, 61 wood pulp only, and 171 both paper and pulp. At the census of 1914 there were 718 establishments with products valued at \$332,147,000. At the census of 1919 the production of paper amounted to 6,124,000 tons, valued at \$682,043,000, as compared with 5,269,000 tons valued at \$291,588,000 in 1914, an increase of 16.2 per cent in tonnage and 133.9 per cent in value.

Products	Quantity (Tons of 2,000 lb.)		Value	
	1919	1914	1919	1914

PAINT AND VARNISH INDUSTRIES

The figures are based upon the returns from 601 establishments primarily engaged in the manufacture of paints with products valued at \$256,714,300, and 229 establishments in the manufacture of varnishes with products valued at \$83,632,400. In addition, paints and varnishes to the value of \$41,559,300 were manufactured by 56 establishments included under other classified industries.

At the census of 1914 there were 585 establishments in the paint industry with products valued at \$112,408,700, 215 in the varnish industry with \$33,215,000, and 57 establishments in other classified industries, making paint and varnish to the amount of \$3,549,700.

PAINTS AND VARNISHES, 1919 AND 1914

	1919		1914

PETROLEUM REFINING

With reference to the petroleum refining industry reports were received from 318 establishments with products for the year valued at \$1,632,354,000. At the census of 1914 there were 176 establishments with products valued at \$396,361,400, an increase of \$1,235,992,000 or 312 per cent.

The phenomenal increase is the result of increase in quantity production and in higher unit values. The output of gasoline in 1919 was 3,637,045,000 gal., valued at \$679,775,500 as compared with 1,195,412,000 gal., and \$106,140,200 in 1914, an increase of 204 per cent in quantity and 540 per cent in value, and in unit value from 8.8c. to 187c. Likewise in fuel oils: the output in 1919 was 7,979,868,000 gal. valued at \$318,082,700 as compared with 3,734,092,000 gal. valued at \$84,017,800 in 1914, an increase of 114 per cent in quantity, and 277 per cent in value, and in unit values from 2.25c. to 4c.; and in illuminating oils the production in 1919, 2,304,850,000 gal. valued at \$235,617,500 was an increase of 191 per cent in quantity and 143 per cent in value over that of 1914, with an increase in unit values from 5c. to 10.2c.

The refineries used 357,686,000 bbl. of crude petroleum (domestic 319,626,600 bbl., foreign 38,059,400 bbl.) in 1919, costing \$866,265,000, as compared with 191,262,700 bbl. (185,027,479 domestic and 6,235,245 foreign) and \$249,728,000 in 1914, an increase of 87 per cent in quantity and of 247 per cent in cost, and in increase in unit values from \$1.31 to \$2.42 per bbl. The marketed production of crude petroleum in 1919 was 377,719,000 bbl., and in 1914, 265,762,535 bbl. Thus the refinery consumption was equal to 84.6 per cent of the domestic production in 1919 as compared with 69.6 per cent in 1914 and 65.9 per cent in 1909.

The gasoline product of the refineries does not include casing-head gasoline made at the wells, except to the extent that it was purchased and used as a material (6,952,200 bbl.). The ranking states, those with products in excess of \$100,000,000, are New Jersey, with 9 establishments; Texas, 38; California, 45; Pennsylvania, 53; and Oklahoma, 66.

Comparative data for the industry in 1919 and 1914 are tabulated in the following table:

PETROLEUM REFINING 1919 AND 1914

	1919		1914	
Products	Quantity 1,000 Gal.	Value \$1,632,354,000	Quantity 1,000 Gal.	Value \$396,361,400

RUBBER GOODS INDUSTRY

Reports were received from 475 establishments in the rubber goods industry having a total value of products of \$1,138,216,000. In 1914 there were 342 establishments with a total value of products of \$300,994,000. Of the 475 establishments reported by the rubber industry in 1920, 96 were located in Ohio; 73 in New Jersey; 56 in Massachusetts; 43 in New York; 32 in Pennsylvania; 26 in Connecticut; 22 in California; 21 in Illinois; 16 in Indiana; 10 in Rhode Island; 9 each in Iowa and Wisconsin; 8 each in Missouri and Oklahoma; 7 in Michigan; 6 in Texas; 4 each in Colorado and Washington; 3 each in Georgia, Kansas, Missouri and Nebraska; 2 each in Maryland, North Carolina, Oregon, West Virginia and Delaware; and 1 each in Louisiana, Kentucky and Maine.

(a) In addition, in 1919, products to the value of \$7,574,000 were reported by establishments assigned to other classifications, and in 1914 to the value of \$752,503.

(b) Not reported in 1914.

(c) Not segregated in 1914 (number of solid tires not shown).

(d) Includes scrap and old rubber (sold or on hand).

SOAP INDUSTRY

Returns were received from 349 establishments which manufactured soap valued at \$317,163,000. In addition soap products to the value of \$21,140,000 were produced as subsidiary products by 90 establishments in other lines of manufactures, making a total of \$338,303,000. At the census of 1914 there were 371 establishments with products valued at \$127,942,000 and 142 establishments with subsidiary soap products to the value of \$7,362,000, a total of \$135,304,000. Although the industry shows a decrease in the number of establishments for 1919 as compared with 1914, the increase in the value of products for all establishments was \$202,999,000 or 150 per cent, primarily due to higher prices.

PIG IRON INDUSTRY

The following figures for the pig iron industry are based upon the returns from 195 establishments with products valued at \$794,466,600. In addition pig iron to the value of \$6,595,800 was produced by 5 establishments included under other classified industries, making a total of 200 establishments, and \$801,062,300 in products. At the census of 1914 there were 160 blast-furnace establishments with products valued at \$317,654,000.

(a) Includes 5 establishments in other lines of manufacture (ferro-alloys, etc.) producing 265,876 tons of pig iron, valued at \$6,595,800.
(b) Includes ferro-alloys (329,580 tons) not included in the pig iron industry in 1919.

INDUSTRIAL POWER AND FUEL CONSUMPTION
IN SUPERPOWER ZONE

A preliminary statement with respect to power equipment and fuel consumption of plants in the Superpower Zone has been prepared by the Bureau of the Census in collaboration with the Superpower Survey of the United States Geological Survey.

The Superpower Zone embraces the North Atlantic area from Maryland to New Hampshire and includes in entirety, Connecticut, Massachusetts, Rhode Island, New Jersey, and the District of Columbia; the southern portion of New Hampshire (Cheshire, Hillsboro, Merrimac and Rockingham counties); the southern portion of Vermont (Bennington and Windham coun-

ties); Kent and New Castle counties in Delaware; Anne Arundel, Baltimore, Baltimore City, Cecil, Herford, Kent, Prince Georges and Queen Annes counties in Maryland; the eastern portion of Pennsylvania extending west to York, Dauphin, Northumberland, Montour, Columbia, Luzerne, Wyoming and Susquehanna counties inclusive; and the southeastern portion of New York, extending west and north to Broome, Delaware, Otsego, Oneida, Herkimer, Fulton, Saratoga, Warren and Washington counties. The superpower project contemplates the development of available water powers to supplement and equalize power requirements, and effect economies in fuel consumption.

The figures are based upon returns from 95,984 establishments. Of these 76,277 or 79.4 per cent used power, the same including 73,694 manufactories, 1,563 laundries, 939 mines and quarries and 31 governmental institutions. The power equipment of these 76,227 establishments aggregated 9,069,471 hp., comprising the following factors:—33,379 steam engines of 4,255,868 hp., 2,115 steam turbines of 1,171,061 hp., 6,246 internal-combustion engines of 279,040 hp., 4,708 water-wheels of 541,033 hp., 506,907 electric motors of 5,336,627-hp. rating (of which 361,961 of 2,770,715 hp. were operated with purchased energy and 198,946 of 2,565,912 hp. by current generated by the establishment), and 51,754 hp. of purchased power other than electric.

The net total is 9,069,471 hp. of rated power equipment, primary and purchased, of which 5,336,627 hp. or 58.8 per cent is represented, as utilized, by electric motor equipment. These establishments consumed 20,910,000 long tons of anthracite, 34,669,000 short tons of bituminous coal and 5,661,000 tons of coke.

Microscopic Examination of Iron and Steel

A COMMITTEE on metallography, appointed by the American Society for Testing Materials, has proposed the following tentative methods for testing iron and steel. Criticism of the methods is invited; it should preferably be addressed to G. F. Comstock, Titanium Alloy Manufacturing Co., Niagara Falls, N. Y.

LOCATION OF TEST-PIECES

The location of the test-piece for microscopic examination is of prime importance. In the case of a casting of steel or cast iron, the section ought to be cut perpendicular to the surface so as to show the variation of structure from the outside to the interior. In the case of forged and rolled metal both cross and longitudinal sections should be examined, their location being determined by the nature of the forging, etc. For crankshafts definite locations are given with reference to the tensile test specimens. For guns, tangential specimens are required and for microstructure these should be cut parallel to the axis, etc. No one specimen is of necessity representative. The usual method of taking a cross-section from rods and bars, while showing segregation of the constituents, fails to reveal the usual lamination, for which a longitudinal section is necessary.

In defective material, the sample should be cut adjacent to the fracture or defect. When necessary the fracture can be protected during grinding and polishing by coating it with a heavy deposit of electrolytic copper, molten lead-tin solder or a mixture of litharge and glycerine. For hardened steel and other material likely to be tempered, fusible metals such as Rose's or Wood's alloys may be used.

METHOD OF POLISHING

The method used for polishing specimens will depend primarily on the material to be examined and on the polishing equipment. In general, samples should not be over 1-in. square and their thickness should be less than the smallest dimension of the polished surface; otherwise there is a tendency to round off the edges.

The softer material can be cut with a saw, while harder metal may be cut with an emery disk or broken off with a hammer. A flat surface is at first obtained either by rubbing on a file held in a vise or by grinding on an emery wheel. In both cases it is necessary to avoid tearing the surface of the metal or causing it to flow. Perfectly smooth surfaces can be obtained by commercial surface-grinding machines.

Having obtained a flat surface in this way, the sample is next rubbed down on a series of emery papers, usually starting with No. 00 Commercial followed by Nos. 0 and 00 French Emery. (Of course, other similar papers of domestic manufacture are also available and suitable for this purpose.) These papers may conveniently be mounted on revolving disks. Rubbing on one paper is stopped as soon as the scratches from the last operation have been taken out. From the No. 00 French Emery the specimen may be taken to a revolving disk covered with broadcloth, preferably running in a horizontal position at such a speed that the polishing powders are not unnecessarily thrown off. For ordinary work, two such disks will be sufficient, the first armed with well-washed carborundum, 65 or a similar grade, while the second may be armed with well-washed alumina. This is cleaner and better than rouge.

To obtain a fine polish it is a mistake to try to save time by hurrying through the papers because if this is done when the specimen is etched innumerable fine lines will be revealed in the ferrite. In some cases the appearance of the ferrite is actually blurred because the metal distorted in the grinding and by the coarse grades of emery has not been subsequently removed. Under no conditions should buffing be tried, because this causes an actual flow of the metal.

For material of small size, such as sheet and wire, numerous methods of mounting have been devised. For wire, various mounting media such as wax, a mixture of litharge and glycerine, fusible metals and the like can be used in a small brass container. For sheet metal, a pack can be built up of pieces of the sample with alternate layers of red fiber board, bakelite or other resistant material, the whole held together by two brass end pieces and two screws.

METHODS OF ETCHING¹

The sample ought to be examined as polished in order to show up the non-metallic inclusions as well as cracks and other defects. In order to show up the structure of the metallic matrix various etching reagents have been used depending on the material being examined. The accompanying list gives the best of these reagents. For general work a 4 per cent solution of picric acid in ethyl alcohol is recommended. This darkens the pearlite in steel and leaves the ferrite or cementite bright as the case may be. Long etching with picric acid in alcohol will develop the grain structure in very low-carbon steel and in wrought iron. This may be done more rapidly with a 2 to 4 per cent solution of nitric acid in ethyl alcohol (95 per cent). For showing up pearlite alone, picric acid in absolute alcohol is best.

To distinguish between ferrite and cementite in high-carbon steels the usual method is to boil in the sodium picrate solution, which darkens the cementite.

For hardened and tempered steel, picric acid may be used, but after etching, washing under the tap and flooding with alcohol, the specimen should be dried by an air blast or if this is not available by shaking it in air. If the usual method of mopping on a soft towel be tried, the etching film will be spoiled.

For the study of hardened and tempered steels under high magnifications other reagents have been devised, such as those of Kourbatoff.

For distinguishing between cementite and phosphide of iron in cast iron, either heat tinting or boiling with sodium picrate may be used, as recommended by Matwieff. This attacks the iron phosphide, but leaves the cementite unattacked.

For revealing the segregation of the phosphorus in steel, various reagents have been used depending on the deposition on copper from a copper chloride solution, as given in the accompanying list of reagents.

In many cases after etching, the ferrite or cementite may be found to be more or less stained or colored. This can often be remedied by a light repolish on a chamois-skin pad. While this brightens up the ferrite or cementite, as the case may be, it markedly alters the appear-

ance of the pearlite, giving it an abnormal structure, and therefore when this method is used, photographs should be so marked.

REAGENTS FOR NORMAL IRON AND STEEL

Picric Acid (Igevsy): Solution (a), 4 g. picric acid in 95 c.c. absolute ethyl alcohol. Solution (b), 5 g. picric acid in 100 c.c. 95 per cent ethyl alcohol.

Nitric Acid: 5 c.c. concentrated HNO_3 in 95 c.c. 95 per cent ethyl alcohol.

Iodine: 1.25 g. I, 1.25 g. KI, 1.25 c.c. H_2O in 100 c.c. alcohol.

Hydrochloric Acid, recommended by Martens and Heyn (1904) especially for hardened steel: 1 c.c. HCl of specific gravity 1.19 in 100 c.c. alcohol. This may be diluted with 500 c.c. water for electrolytic etching with a very weak current.

KOURBATOFF'S SOLUTIONS FOR HARDENED STEEL

Solution A: 4 c.c. HNO_3 in 96 c.c. amyl alcohol, acting five minutes, will color troostite brown, austenite yellow, martensite white.

Solution B differentiates the various constituents. It consists of 1 volume of saturated solution of ortho-nitrophenol in alcohol, and 2 volumes of 20 per cent HCl in amyl alcohol.

Solution C: Mix just before using a solution of 4 per cent HNO_3 in acetic anhydride with three times the volume of a mixture of equal parts of amyl, ethyl and methyl alcohols. It colors troostite and troostite-sorbite.

Solution D: 1 volume of 4 per cent HNO_3 in ethyl alcohol plus 3 volumes saturated solution of nitrophenol in ethyl alcohol; immersion of ten minutes colors troostite and martensite needles.

Solution E for troostite: 2 parts methyl alcohol, 2 parts ethyl alcohol, 2 parts amyl alcohol, 1 part butyl alcohol, 3 parts of 4 per cent HNO_3 in acetic anhydride.

Solution F: 4 per cent HNO_3 in methyl alcohol to which $\frac{1}{10}$ of its volume of 4 per cent picric acid in ethyl alcohol is added. Colors austenite, martensite and troostite differently.

Solution G: 1 volume of HNO_3 in alcohol and 3 volumes of saturated solution of nitraniline. Colors troostite, troostite-sorbite and martensite needles.

Benedicks' Solution: 5 per cent meta-nitrobenzol sulphonic acid in alcohol. Darkens martensite more than austenite after immersion of fifteen seconds.

SOLUTIONS FOR CARBIDES

Kourbatoff: 2 g. picric acid, 25 g. NaOH, 75 c.c. water. Cementite will be colored after boiling five to ten minutes. Ferrite and tungsten carbide (WC) are unattacked. Various other compounds, such as Fe_nW and $\text{Fe}_2\text{W}_2\text{C}$, are colored.

Matwieff: Boil specimen twenty minutes in a neutral solution of sodium picrate, and wash thoroughly. Iron phosphide is attacked, but cementite is not.

Yatsevitch: Tungsten carbide in high-speed steel is darkened by immersing ten to twelve minutes in a fresh mixture of 10 c.c. commercial H_2O_2 in 20 c.c. of a 10 per cent water solution of NaOH.

Hilpert and Colver-Glauert: Non-pearlitic steels and pig iron may be etched for from seven seconds to one minute in 3 or 4 c.c. saturated aqueous solution of SO_2 in 100 c.c. alcohol or water.

Murakami: Carbide and tungstide in high-speed and tungsten steels may be distinguished by a hot solution of 10 g. potassium ferricyanide, 10 g. KOH and 100 c.c. water.

SOLUTIONS FOR ALLOY STEELS

Austenitic nickel steels may be etched in 5 g. Fe_2Cl_6 , 50 c.c. HCl and 100 c.c. H_2O .

Stellite and high-chromium steels may be etched with a very weak electric current in a 0.5 per cent NaOH solution.

On 110-volt circuit use two 4-cp. lamps in series, connected with two-wire terminal (platinum wire preferable). Flood surface of specimen with solution, and make contact with one wire at side and dip the other in the solution, moving it around to obtain uniform etch.

METHODS FOR IDENTIFICATION OF NON-METALLIC INCLUSIONS

Stead² uses 30 per cent H_2SO_4 . Bubbles arise from sulphides, but none from silicates or oxides.

Law³ uses an acid solution of lead or cadmium salt in gelatine. The sulphides form deep brown or yellow stain of cadmium or lead sulphide. Oxides or silicates unaffected.

MEANS FOR THE IDENTIFICATION OF NON-METALLIC INCLUSIONS

As Polished	
FeS.	Brownish yellow.
MnS.	Slate blue, smooth.
FeS_xMnS_y	Slate blue to brown, may show duplex structure.
FeO.	Slate blue, rough, a little darker than MnS.
MnO.	Similar.
Mn-silicate.	Greenish tinge, smooth and greasy.
Fe-silicate.	Black and greasy.
Al_2O_3 .	Tiny hard rounded grains, never elongated by rolling, etc.
Sand grains.	Angular form, convex side, greasy appearance standing in high relief.
Titanium nitride or cyanonitride.	Pink or yellow cubic crystals.

He also recommends as an electrical etching solution consisting of distilled water with 0.002 per cent ammonium chloride or caustic potash, used boiling. After a few minutes wash and dry with alcohol. Results: MnS unaltered. FeO and FeO_xMnO_y is reduced, but MnO unaffected.

Matwieff⁴ uses hydrogen or steam at 600 deg. C., or organic acids to distinguish oxides, silicates and sulphides as follows:

	Oxides	Silicates	Sulphides
Hot hydrogen	Reduced	Unaffected	Unaffected
Hot steam	Attacked	Unaffected	Unaffected
Organic acids	Unaffected	Unaffected	Attacked
2% HF in absolute alcohol ⁵ .	Unaffected	Darkens	Darkens

Iron oxide may be distinguished from manganese oxide by repolishing the sample reduced by hot hydrogen, and etching with dilute solution of FeCl_3 in alcohol. If colored feebly, the inclusion is FeO; if colored deeply, it is MnO with some FeO; MnO alone is not reduced. Iron sulphite is colored by tartaric acid, while MnS is very feebly colored.

SULPHIDES

Rohl⁶ recommends a 1 per cent solution of acetic, citric, oxalic or picric acid in water, noting that picric acid gives the most uniform results on sulphides. FeS is always readily blackened in one minute; MnS is slightly blackened in forty-five seconds. Sulphides also give a dark brown color after a triple etching (a) 4 g. picric acid in 100 c.c. amyl alcohol, (b) 4 c.c. HNO_3 in 100 c.c. amyl alcohol, (c) concentrated hot NaOH. A 2 per cent sodium acetate will give FeS a brownish tint in one minute, whereas MnS is colored but very lightly.

Reduction tests for sulphides: Sulphides are covered by mercury after immersion in HgCl_2 solution. If the sample is lightly repolished, FeS will be found corroded but MnS not. A 3 per cent boiling solution of AgNO_3 will color FeS a uniform violet blue and MnS a slightly darkened dove gray. On repolishing, FeS appears a reddish violet, and MnS a blue gray.

Campbell's method of distinction: A short preliminary etching with 1 per cent picric acid in ethyl alcohol, followed by tempering to dark yellow, changes FeS into a beautiful dark blue to reddish violet, and MnS into dull gray to bright white.

Whitely recommends that 5 g. gelatine be soaked one hour in 20 c.c. water and 15 c.c. gelatine added. Heat till clear, add 0.05 g. tartar emetic in 1 c.c. H_2O , filter, and add 1 c.c. dilute H_2SO_4 . Apply warm. Yellow ring forms around sulphides.

McCance⁷ replaces tartar emetic by 0.1 g. AgNO_3 , when a black stain indicates sulphide.

Comstock⁸ uses boiling alkaline picrate of soda. MnS is blackened and roughened, while silicates and oxides are unaffected.

Hardened Rosin and Resin Esters

A Study of the Special Treatment of Rosin for Use in Tung-Rosin Varnishes—Empirical Methods Now in Use Should Be Replaced by Better Technology and Chemical Control—Description of Experiments to Determine Optimum Conditions for the Esterification

BY ALEXANDER MURRAY

WITHIN the last decade or so the art of varnish-making has been completely revolutionized by the extensive introduction of tung or chinawood oil varnishes. Previous to this time much rosin had been used for the adulteration of varnish gums, and, in the form of "gloss oil," as a cheap and deleterious addition to paints and enamels. Gloss oil is a solution of lime-hardened rosin in benzine.

It has been realized for some years that rosin has wonderful adaptability in combination with tung polymers for the production of varnishes of great and varied utility, having remarkable properties and fair durability. The outstanding characteristics of tung-rosin varnishes are extremely pale color, great rapidity of drying, high gloss, waterproof properties and very fair durability. Accordingly rosin has risen from the position of a despised adulterant to a necessary raw material of extensive applicability. Tremendous quantities of these varnishes are used today. Some are simply tung rosin and thinners; others contain proportions of linseed oil or other oils or resins.

Untreated rosin is not satisfactory for this purpose for many reasons. It is too soft, too acid and neither waterproof nor durable. Raw rosin feels sticky or tacky, even in the heat of the hand. Its softening point is about 70 deg. C. The acid number averages about 160. When exposed to moisture it turns milky white, probably due to penetration of moisture with the formation of an emulsion film on the surface. Rosin is a plastic, non-crystalline solid. It has sometimes been called a colloid, though probably on insufficient evidence.

The present paper deals with the special treatment of rosin, in relation to its use in tung-rosin varnishes. It will be seen that even in this one phase of varnish making there is a fascinating field for research. While there has not been an absence of chemists in the industry, they appear to have concentrated most of their efforts on the testing and analysis of varnishes and raw materials, rather than undertaking research with a view to developing a scientific rationale for the manufacture of their products. There is, of course, great opposition from the professional varnish makers, who in general seem to feel that their interests are best served by a policy of secrecy.

UNTREATED ROSIN IN VARNISH

If rosin is dissolved in benzine and this solution then brushed out on some surface and permitted to dry, it will be found that when the thumb is pressed down firmly upon it the film will appear tacky. This tackiness persists when raw untreated rosin is used as a major ingredient in the preparation of a varnish. The latter might appear to dry satisfactorily, especially in cold weather, but in a warm room or on a hot summer day, if one were to be so unfortunate as sit in a chair

that had been finished with it, he would be likely to experience the embarrassing fear that an essential section of his clothing was not coming with him when he started to arise.

The untreated rosin varnish may have a remarkably high gloss when applied, but it becomes dulled rather rapidly. This varnish also gives inferior service outdoors. Gardner has shown that it is entirely unsuitable for concrete and cement paints, because of its very high acid number.

NECESSITY FOR TREATING THE ROSIN

It is apparently assumed by some that a combination occurs between the wood oil and rosin, with the resultant production of a new compound of indefinite composition. There is no real evidence, however, that any such reaction occurs, and, on the contrary, observation indicates that no combination occurs between the rosin and tung polymers other than physical interdispersion, and that the properties of the rosin are not changed in any absolute sense, but only modified or diluted by the presence of the tung oil. The heating to which the colophony is subjected in the cooking of the varnish is insufficient to change its characteristics to any marked extent, and such change, contrary to some opinions, tends actually to soften besides darkening it. In some recent experiments the writer found that after heating rosin for one hour at 300 deg. C. the softening point had been lowered 2 deg. C. and the acid number reduced to 149. Since it is well known that on distillation rosin breaks down into lighter distillates, rosin oil and tar, a lowering of melting point should be expected when it is heated to incipient distillation for any length of time. When the varnish is to be used in conjunction with pigments, there is an additional reason why the rosin acids must be neutralized, since the latter are adsorbed by basic pigments and in time combine with them chemically. (The author hopes to present some evidence for this statement in a future paper.)

EMPIRICAL METHODS FOR HARDENING ROSIN

It is desirable, therefore, to treat rosin for the two fundamental purposes of increasing the melting point and neutralizing it; this can be done either as a part of the varnish-making process or as a separate operation. The expression "hardened rosin" is technically applied only to rosin which has been neutralized with lime. There is much difference of opinion among varnish makers as to the kind of lime to use, and the technique—such as temperature, stirring and method of adding lime. Ask half a dozen expert varnish makers the correct way to harden rosin, and you will get half a dozen different methods.

It was formerly generally supposed, and is today still

affirmed by many, that oyster-shell lime has no equal for this purpose. The investigator constantly uncovers dogmas that might cause in him a tendency to smile, but most fetishes have some foundation in fact, and this one is a good illustration. Oyster-shell lime is weaker in CaO content than a good grade of hydrated chemical lime, but is technically free from iron and magnesia, and of course its composition is reasonably constant. Many commercial limes contain appreciable amounts of iron, which is taken up by the rosin and discolors the product. As for magnesia, its effect is peculiar, due to the fact that solutions of magnesium rosinate have much higher viscosity than solutions of the calcium salt. Very small proportions have a noticeable thickening action, which is highly undesirable, since the tung polymers themselves have great viscosity. The magnesium salt is much less fusible than rosinate of lime, which presents an additional disadvantage if the MgO content is high. A suitable lime should not contain over 1 per cent of MgO, and should be technically free from iron.¹

It will be readily appreciated from the foregoing that the empirical varnish maker, without chemical control, might be very badly impressed by a change from oyster-shell lime to one of unknown composition.

The details of neutralizing would appear to be of the simplest order, but here one is surprised to find frequently that the more complexity and mysticism one can add to the process the better will be the ultimate result. The following is a typical formula: "Melt 400 lb. of rosin in a copper kettle, raising the heat to 500 deg. F.; sift in 32 lb. of oyster-shell lime. Do not stir the mix. Raise the temperature to 550 deg. F. and hold there until the lime is taken up, then remove from fire."

Hot rosin darkens rapidly in contact with the air, and since pale color is ever desirable and since nothing is gained by high temperatures, it should be subjected to only the lowest practicable temperatures for the shortest possible time. This rule should be observed at all times when cooking rosin. It darkens more quickly than heated oils, and therefore it should be added to the batch of varnish at as late a point in the cooking as possible. When using 6 lb. of lime to 100 lb. of rosin, the latter may be heated to 400 deg. F., the lime then added (it need not be sifted) and thoroughly stirred in for about ten minutes, when the operation will have been completed.

PREPARATION AND USES OF PALE HARDENED ROSIN

It is not possible to prepare pale hardened rosin with much less than 30 per cent of free rosin, because of the high melting point of the rosinate, and in order to get even this degree of neutralization it is necessary to cook the rosin with 9 lb. of lime per 100 lb. of rosin at a temperature of 435 to 440 deg. F. for one and one-half hours. In this case one would, of course, keep the kettle covered during the cook.

Rosin can be subjected to a great deal of cooking in covered aluminum kettles without darkening at all, and the rosin acids do not appear to attack the metal to any marked extent. If the hardening is being conducted as an integral part of a varnish cook, the next ingredient is added as soon as the lime is combined;

and if being limed separately, the hardened rosin is ladled into shallow pans to cool, and then broken up and stored for future use. The advantage of liming large batches of rosin at a time is, of course, primarily the saving of labor and fuel, but it also facilitates uniformity, since it is possible for the laboratory to follow the neutralization closely, and make corrections when necessary. In cases in which the oils have to be cooked for an hour or longer it is advisable, from the point of view of the color of the product, to have the rosin already hardened and add it at a late stage of the cooking.

Hardened rosin varnishes are still unsuitable for use in concrete, plaster and cement coatings, since they contain considerable free rosin acids. They also caused serious thickening when used with zinc oxide and some white leads and lithopones before this reaction was better understood. Furthermore, hardened rosin is very brittle and imparts this property to a varnish to an extent proportional to the amount used.

RESIN ESTERS AND THEIR PREPARATION

The preparation of esters of the resin acids has received attention for some time, and glyceryl triresinate is being used extensively. By this method the rosin acids can be completely neutralized if desired.

There are on the market resin esters known as "ester gums," some of which are very pale in color and are said to have been vacuum-distilled. It has been found that some of these darken readily when cooked and that the resulting varnish is not lighter than that prepared from esters made in the varnish kettle in the manner described below.² The latter esters have the additional advantage of lower cost.

The reaction, of course, is well known. The amount of glycerine required by theory is about 10 per cent of the rosin, although the author has found as high as 20 per cent being used in practice. Gardner³ used 55 lb. of glycerine to 100 lb. of rosin, but did not get a triglyceride, as will later be explained. Free glycerine is very undesirable in a varnish, as it reduces the resistance to moisture and causes rapid deterioration of the film, especially with exterior exposure. It is further necessary to use a minimum amount for economic reasons, glycerine being usually the most expensive ingredient in the formulas in which it is used.

OPTIMUM TEMPERATURE

In the writer's experiments to determine the optimum conditions for esterification, temperature received first consideration. When glycerine is added to melted rosin at 150 deg. C., combination is seen to commence immediately, as evidenced by the formation of water in the mixture, which causes some foaming and apparent ebullition. The fused material is clear, but drops removed and cooled will show a milky appearance. The acid number is found to decrease rapidly, but one may cook at 150 to 250 deg. C. for hours and a large part of the rosin will still remain unneutralized, no matter how great an excess of glycerine is used. Now, if the temperature is raised to 290 deg. C., the boiling point of glycerine, the last portion will rapidly combine and an almost neutral ester will result.

It is necessary to keep the batch covered during

¹See also H. A. Gardner, "Lime for the Varnish Industry," Circular 113, Educational Bureau, Paint and Varnish Manufacturers' Association, for a comparative discussion of the properties of many commercial limes.

²The author's work on esters, reported herewith, was completed before the publication of Gardner's paper on "Tunga-resin."

³See "Papers on Paint and Varnish," p. 234. See also p. 214 for patent literature.

esterification, in order to prevent excessive discoloration and loss of the glycerine, which is readily carried off by the water vapor. It is not advisable to use a condenser of course, as the steam must be permitted to escape.

The result is a glyceryl triresinate, which, if carefully prepared, will have an acid number of less than 5. This ester, however, has a somewhat lower melting point than the original rosin, as might be expected from our previous experience with other organic esters. Accordingly the ester is slightly more tacky than the rosin itself. It is the opinion of the author, although he has not yet had sufficient confirmation to state it as a fact, that after the ester has been combined with the tung polymers, its tackiness is not as pronounced as the stickiness of rosin and that the film has a softness that makes it more durable in certain uses, notably in furniture varnishes and exterior coatings. Such a varnish is very elastic and waterproof and practically neutral, and is of value in the preparation of paints for concrete, cement, and plaster surfaces.

The addition of 0.5 per cent of a cobalt drier has been recommended to overcome the tackiness of rosin ester, but this quantity would represent an excess of a powerful drier, to be avoided on general principles, and besides would cause serious darkening of the product. The melting point of rosin ester is raised in practice when desired by the addition of a small amount of lime or some hard resin, such as Congo copal.

TIME OF ESTERIFICATION

After determining the optimum temperature the next factor to be ascertained was the time. In this connection it was found that, esterifying at 555 deg. F., the reaction passed through a peak about fifteen minutes after this temperature was reached. Working with 12 lb. of glycerine to 100 lb. of rosin, a resin ester with an acid number of 5 to 10 was obtained in that time, and if heating was continued there resulted a gradual increase in acidity, due apparently to decomposition of the ester after the excess of glycerine had been consumed. This is analagous to the action of the glyceryl esters of the higher fatty acids, such as those of linseed oil, which decompose under prolonged heating with the accumulation of increasing quantities of free fatty acid. The latter are more stable than the resins. A sample of linseed oil will reach an acid number of about 20 after heating for, say, five hours at 575 deg. F.

It is necessary, then, for the varnish maker, with the aid of his control laboratory, to determine the peak of his esterification and stop cooking at that point. It is desirable not to use sufficient excess of glycerine to neutralize the rosin completely, but to use not more than 12 lb. of glycerine, and when the neutralization has proceeded to the maximum, stir in half a pound of lime and remove the kettle from the fire. The resulting ester will be practically neutral, and the small amount of lime contained will act beneficially as a hardening agent.

The complete procedure can be illustrated by the following example:

Melt 600 lb. of rosin in a copper or aluminum kettle, and when the temperature reaches 400 deg. F. slowly add 72 lb. of glycerine—it is not necessary to stir, as the liquid is strongly agitated by the escaping steam. Increase the temperature to 555 deg. F. and hold it there for about twenty minutes or the exact time that

is found to give maximum esterification, which may vary slightly with different apparatus and materials. Then stir in 3 lb. of lime, remove the kettle from the fire, and ladle the ester into cooling pans.

ADDITION OF CONGO COPAL

We have previously referred to the addition of Congo gum as a hardening and toughening agent. This is a hard fossil resin, melting with partial decomposition at a high temperature and having an acid number of about 133. The esterification of Congo copal presents considerable difficulty, as it will not melt at 555 deg. F., and glycerine cannot be used in unsealed kettles at higher temperatures.

The addition of 10 per cent of Congo to rosin ester was found to improve the latter greatly, adding considerable toughness and hardness. This addition can be accomplished by cooking 90 parts of rosin with 10 parts of Congo, keeping the kettle covered, at 600-610 deg. F. until the Congo is completely dissolved in the rosin. No rosin can be esterified unless it is in a liquid condition. When the Congo is entirely melted, the batch is cooled to 550 deg. and 12 parts of glycerine added. The temperature is then raised to 555 deg. F., and the remainder of the procedure is the same as with pure rosin.

CATALYTIC POLYMERIZING ACTION OF COPPER

Working along the same lines with increased quantities of Congo in a copper kettle, it is found that severe darkening takes place, accompanied by uncontrollable foaming, which increases with the amount of the hard gum used. When a proportion of two parts of Congo to one part of rosin was reached, the mass became very dark and solidified before the glycerine could be combined. This solidification occurred very rapidly at 555 deg. F. and strikingly resembled the polymerization of tung oil. After several unsuccessful attempts to control the reaction in copper the experiment was repeated in aluminum, with the result that foaming and darkening were negligible and the ester remained liquid until the end of the operation and could then be readily poured or ladled from the kettle. It is possible to make esters in aluminum with three parts Congo to one of rosin, using 10 lb. of glycerine per 100 lb. of resins. The resulting ester has a hardness approaching that of Kauri, an acid number of 7.5 or less, and lends itself to the preparation of varnishes which are paler in color than those which can be made from Kauri. As a result of these experiments it is obvious that copper acts as a polymerization catalyst on Congo copal.

In regard to the covering of the kettle while melting and cooking resins, it should be noted that unless the cook is very short, air should be excluded as much as possible to prevent darkening of the product. It is interesting here to contrast the well-known fact that linseed oil shows a maximum darkening if it is cooked in the total absence of air—e.g., in an inert atmosphere—and also darkens considerably if cooked in a covered kettle.

The writer regrets that lack of facilities and time has prevented his accumulating more exact scientific data on the reactions and properties of the materials discussed in this paper, but would suggest that here is a practically virgin field for research of real and immediate value.

Springfield, Mass.

An Improved Type of Filter Press

Comparison of Advantages and Limitations of Various Types of Filtering Apparatus and a Description of a Modified Form of the Plate and Frame Filter Which in Certain Features Appears to Present a Number of Important Improvements

BY CHARLES D. BURCHENAL
Consulting Engineer

THERE is no single type of filtering apparatus which can be used to the best advantage for all classes of filtration work. Although the plate and frame filter press is capable of performing a great many filtering operations, it requires hand labor and is intermittent, so that if conditions permit some other filter which will give continuous operation or a reduction of labor would have certain advantages. These economic advantages, however, should not be permitted to blind one to certain inherent faults in such a filter, and in each filtering problem all conditions should be studied and the proper apparatus determined by a process of elimination.

The following order of considerations is suggested:

First. When the material is of a free filtering nature, containing no heavy particles or any colloidal matter to plug up the pores of the filter cloth, it is obvious that some form of rotary vacuum filter should be used in order to take advantage of continuous operation and the elimination of labor in dumping.

Second. When high pressures are desirable and when the solid matter is not to be recovered in dry form, the rotary pressure filter may prove suitable, and although the operation is no longer continuous and the advantage of automatic discharge is lost, the labor of discharge is less than with plate and frame filter.

Third. When a solid cake is required, no more simple and effective apparatus has been devised than the plate and frame filter, which since its invention fifty years ago has increased in usage and is today the most widely used type of filter.

INHERENT ADVANTAGES OF THE PLATE AND FRAME FILTER

The inherent advantages which are responsible for its popularity are simplicity, ruggedness, cheapness and a compactness that gives the greatest possible filtering area for the size of the machine. Cloths are easily removed and replaced without any sewing or wastage. Cakes, being inclosed, cannot get away from the positive flow of wash water or drying air, which may be supplied at high pressures. There is practically no filtering operation which cannot be accomplished by the plate and frame machine, but it has the disadvantage of requiring hand labor to dump and dress its frames, and it is this that has inspired the design of every attempted substitute.

USE OF THE FILTER PRESS IN THE SUGAR FACTORY

One important use of the filter press has been in the treating of settlings from the raw juice of sugar factories. Here the hot filtrate and hot washings must be recovered with a minimum loss of heat and with as much speed as possible (to prevent inversion of the sucrose) and the cake must be recovered in dry form for use as

fertilizer. Furthermore the material contains cane wax and colloidal matter, which necessitates the frequent removal and washing of the cloths in a laundering machine with hot water. It would appear, therefore, that any filter having its cloths sewed or fastened in place is seriously handicapped for this work.

A decantation system has recently been proposed for this use and installations have been made in a number of foreign countries. However, the element of time required and the possible failure to remove lighter suspended particles have caused the desirability of the scheme to be questioned by some sugar engineers, for these two points are of greatest concern to the sugar boiler—viz., the inversion loss of sucrose through delay in the dilute stage and the presence of impurities in the resulting massecuite, which prevents the recovery of the otherwise crystallizable sugar.

DESIGN OF AN IMPROVED FILTER

Realizing its importance, the writer has made a study of the plate and frame filter for the past few years and has developed a form which eliminates some of its disadvantages and at the same time simplifies the already comparatively simple machine. This improved type of filter press has been given the trade name Duplex, since it employs double inlets, double outlets, and a new method of supporting the cloth which gives (in the early stage of the cycle) practically double the usual filtration rate. Due to a special support for the cloths which allows the free passage of filtrate at all times, cakes may be formed of unusual thickness, thus reducing the labor, since the filter is dumped at less frequent intervals. A double system of washing is provided so that all cakes may be washed (in alternate directions if desired) by

FIG. 1. SURFACE OF CAKE OBTAINED WITH PYRAMID SURFACE. PLATE SHOWING DEPTH OF INDENTATIONS

the manipulation of a single valve. It is not necessary to close drip-cocks on every alternate plate, as is usual in a washing type press, and all plates are exactly alike. Drip-cocks have been eliminated as well as the open drip gutter, yet turbid filtrate from any one cloth can be detected and shut off without stopping the flow from a perfect cloth on the opposite side of the same plate. The absence of drip-cocks simplifies the operation, and

FIG. 2. COMPARISON OF SECTIONS OF CHAMBERS IN USUAL TYPE OF FILTER PRESS AND IN DUPLEX TYPE

the substitution of a closed discharge for the open gutter saves the loss of heat, or loss by evaporation where volatile filtrates are handled. It also enables the operator to stand closer to the press, and in large units permits of mounting the press closer to the floor, giving easier handling and cleaner discharge of cake into floor hoppers.

WIRE SCREEN SUPPORT FOR CLOTHS

In the usual form of filter press the cloths are supported on plate surfaces consisting of corrugations or a series of truncated pyramid projections cast on the plate, and as the cloths become coated and the pressure is consequently increased, they are pressed against the tops of these projections with such force that there may be no flow through the cloth at these points and the effective filtering area is decreased by the aggregate area of these points. As the pressure is further increased, the cloth is stretched and forced down between these points until it tends to lie against the web of the plate itself and actually does so where the pressure is sufficiently high, as can be seen by noting the depth of the corresponding corrugations on a hard cake, such as is shown in Fig. 1. Where the grooves are abnormally deep, actual contact with the web is probably never reached, but the condition is approximated. This condition not only further reduces the effective filtering area at the time when it is most needed but hampers both the run-off of the filtrate which does get through the cloth and the supply of wash water during the subsequent washing operation, since these constantly decreasing "valleys" behind the cloth are the only means of carrying away the filtrate to the drip-cocks and of admitting wash water to the cake surface. It is for this reason that with many materials the filtrate will

cease to flow before a solid cake is formed and the thickness of the frames employed must be made smaller in order to obtain a solid cake.

In the Duplex press the cloths are supported on a special screen of wide mesh double crimp wire, which in turn is carried on widely spaced reinforcing ribs cast on the plate, so that ample space behind the cloth is provided for the fall of filtrate and for the easy access of wash water to the entire surface of the cake. No matter how much the cloth may stretch it cannot come in contact with anything except the surface of the wire, which is small and gives practically no reduction of the effective area.

COMPARISON OF RATES OF FILTRATION

So many variable factors enter into the rate of filtration that values obtained with one material are of little value for comparison with those derived with another in establishing the efficiency of a filter. The rate is constantly changing throughout any single operation and even the fairly definite value of average gallons per square-foot-hour for the cycle may vary on the succeeding run of the same material, in case it is of such a nature as gradually to clog the cloth pores. The graph shown in Fig. 3 is useful for showing comparative rates, only because both types of plates were supplied from the same pump, filtering simultaneously. For this test a single Duplex unit and a single pyramid surface unit were mounted in a press, supplied from a small laboratory triplex pump running at a constant speed with a relief valve set at 40 lb.

The material used was spent filter-cel mixed with bag fiber and other matter filtered from raw sugar washings in the leaf filters of a refinery. These solids settled rapidly and in passing over the large inlet openings to the

Areas per plate, 14.6 sq.ft. Vol. per frame, 1.22 cu.ft.

frame nearest the pump settled in this frame enough to give the increase in density shown on the Duplex curve, where it will be noted that the solid cake was formed with the smaller volume of filtrate. These units being supplied from a constant rate pump, the filtration rate

of the Duplex plate could of course never exceed this small rate, so that the higher rate which is possible is not shown, as it would be if a monte-jus or centrifugal pump has been used.

The centrifugal pump is the ideal method for filter supply, as it gives a large volume of filtrate when the resistance is low and automatically increases the pres-

FIG. 4. FRAME SECTION SHOWING FOUR INLET PORTS AND ESCAPE OF AIR

sure as the flow diminishes. It is also free from pulsations which tend to compact the deposit on the cloths and it can never raise the pressure above its characteristic value to a dangerous point by failure of a relief valve. Each press should have its individual pump in order to get the most service from it. Where several presses are served from one pump, the empty press on being connected to the supply line will take most of the flow, as it offers the least resistance, and the other partly filled presses must stand idle until the new press has caught up with them in resistance. The resistance of the fresh press may be equalized by throttling it, but this of

FIG. 5. VIEW OF PLATE SHOWING INCLOSED FILTRATE OUTLETS

course cuts down the higher rate which is possible with the fresh press.

PRECAUTIONS AGAINST BREAKAGE OF PLATES

The breakage of plates is almost invariably caused by a difference of pressure on opposite sides, due to the plugging up of the inlet to the adjacent frame with some fibrous or foreign substance. This is a rather frequent occurrence in the usual type of press when used with material containing fiber, for the inlet to the frame consists of a single slot, which is necessarily narrow on account of the thin frame used.

The wide frames and the use of double feed channels in the Duplex press make it possible to provide four wide, flaring inlet openings to each frame, so that it is impossible accidentally to cut off the pressure in any one frame. Further insurance against breakage is given by the use of a stronger plate, which is obtained without increase in the metal by casting continuous reinforcing ribs diagonally across the plate, those on the back side of the plate running perpendicularly to those on the front side.

The use of two inlet channels in the upper corners has the further advantage of allowing the venting of air through one as it is displaced by the incoming liquid through the other when first filling the press (Fig. 4), thus avoiding the usual air-bound condition at the start. The full area of the cloth is thus used from the very start instead of being held back until the entrapped

FIG. 6. DIAGRAM OF REVERSE WASHING SYSTEM

air has had time to bubble out of the drip-cocks along with the filtrate or seep through the cloth joint at the top of the press.

The use of two outlet channels at the bottom corners allows an ample area to carry away the filtrate when running at its maximum rate, as each plate, instead of being drained through the usual $\frac{1}{2}$ -in. cock, has two outlets, each equivalent to a $\frac{3}{4}$ -in. cock.

Another novelty of design consists in the way these outlets are connected to the plate faces. The drainage from the front face of every plate is connected to the right-hand channel and to this one only, while the back face of every plate is connected to the left-hand channel only. These individual connections are made by bringing the filtrate out of the press at the edge of the plate through a short sight-glass and back again into the internal channel. In this way any defective cloth may be detected and its flow shut off by means of a stop-cock, while the flow from the cloth on the other side of the same plate may continue if desired.

These stop-cocks are merely a precaution in case of

defective cloths and are never opened or closed except in this emergency. In fact, where this risk is negligible, the stop-cocks and sight glasses may be dispensed with entirely without affecting the operation of the press.

In the usual press with drip-cocks, which is provided with a wash-water channel (opening into every other plate) the shutting off of turbid filtrate at any one cock will force the dirty liquid back into the washing channel, whence it will run out of the adjacent drip-cock. Consequently the whole set of drip-cocks is utterly valueless in this type of press as far as the stoppage of turbid filtrate is concerned. Some manufacturers have gone to the expense of providing a ball-check valve on each wash plate in order to prevent this.

REVERSIBLE WASHING SYSTEM

By admission to the lower left-hand eye, the wash water comes in contact with the entire front surface of each cake, whence it flows straight through the cake and

FIG. 7. CYCLE OF OPERATIONS WITH DUPLEX FILTER

out at its back surface into the space behind the cloth which drains into the lower right-hand eye. By admitting water to the left-hand eye and draining from the right, the cakes are all washed in the opposite direction—from back to front. Thus the flow may be reversed as often as desired by the handling of a single valve.

The inlets in the upper corners of the frames may also of course be used for washing, thus making it possible to apply water at all four corners in cases where this is of advantage.

In drying the cake compressed air may be admitted at the upper corners, driving the moisture out at the bottom, or it may be admitted at one of the lower eyes, blowing transversely through the cake and out the other lower eye.

The cycle of operations is shown in Fig. 7.

COMMERCIAL INSTALLATIONS

The original installation of a press of this type was made in a Hawaiian sugar factory and consisted of four hydraulically operated units, each forming forty cakes, 40 in. square of 4 in. in thickness—a capacity of 142 cu.ft. and having a filter area of 848 sq.ft. per unit. (See Fig. 8.)

These large frames are mounted on rollers and may be handled by two men, so that the labor cost is no more than in a small press and the labor per unit of solid is vastly decreased. Since the time of the original instal-

FIG. 8. ORIGINAL INSTALLATION OF DUPLEX FILTER

lation several improvements in the design of the press have been made. The filter is patented and is now being manufactured by T. Shriver & Co., of Harrison, N. J.

The latest installation (July, 1921) has been made by the American Sugar Refining Co. for use on the recovery of spent filter-cel from sluicing of leaf filters. These sluicings contain large amounts of jute fiber from sugar bags, which caused frequent breakage of plates, and it is the prevention of this which makes the machine of special value in this case.

With the perfect joint surfaces and the effective closing device of the modern filter press, the drip from the elements is negligible, but in this installation drip-sheets are provided as a precaution to prevent any drip into the floor hoppers, for the solid must be delivered as dry as possible to save the expense of evaporation in the subsequent retorting operation.

The drip-sheet used is turned up at its lower edge, forming its own gutter, which drains to a small sump at the end of the press. The sheet is split longitudinally

FIG. 9. DIAGRAM SHOWING ARRANGEMENT OF PIVOTED DRIP SHEETS

in two halves, each carried on a shaft running parallel to the axis of the press, turning in bearings on the press legs at either side. This gives a single overlapping joint down the middle when the sheets are in place, and when

not in use these halves swing down into the floor hopper, forming extensions to its sides above the floor line, assisting in the clean discharge of cake and preventing the necessity of the usual removal of the sheet in transverse sections.

It is believed that the use of some decolorizing carbons may be simplified by the application of the Duplex principle, for the liquid may be readily passed and re-passed transversely in alternate directions through large volumes of carbon in the form of abnormally thick cakes. When exhausted, these may be washed and dumped, regenerated and reformed into cakes ready again for treating the liquid to be passed through them. This method is of course applicable only to vegetable carbons having a rapid decolorizing action.

One of the principal points in favor of the Duplex filter is that it has obtained its added efficiency by a simplification, rather than a complication, of the well-known plate and frame apparatus.

Book Reviews

GASOLINE AND OTHER MOTOR FUELS. By Carleton Ellis and Joseph V. Meigs. 710 pp., 206 illustrations. New York: D. Van Nostrand, 1921. Price, \$10.

The authors, Ellis and Meigs, have written a book for which there is undoubtedly a very great need. For several years past, processes for the manufacture of gasoline by various novel and usually startling methods have appeared in the newspapers, which have served no other purpose than to separate a few people from good money, and to arouse the idle curiosity of the commuter on his morning train. The authors are well known for their technical contributions and their volume on "Gasoline and Other Motor Fuels" contains admirable chapters calculated to explain what gasoline is, how it is obtained in the usual refinery practice, and how it is refined and tested. There is also an excellent discussion of the relative importance of benzene from by-product coke-ovens and other minor sources. There is also a very excellent discussion of the value of alcohol as a motor fuel and the possibilities in the distillation of oil shale, both of which subjects are bound to become of increasing importance. In fact, the only criticism which the reviewer can make of the present volume is the modesty of the authors in not being more critical of some of the subject matter, particularly the excerpts from the patent literature, which they include. In Engler's ponderous volumes on petroleum, it was evidently attempted to include all matter which found its expression in print and to present it to the reader impartially and without criticism and thus put it up to the reader to discern and select sense from nonsense. This seems to be one method of writing or rather compiling books on technical subjects. In justification of this method, it is sometimes said that an experienced investigator may get valuable ideas from the failures of others. However, it is probable that most persons referring to the work of Ellis and Meigs for information will be confused by a mass of descriptive matter taken largely from the fiction leaflets put through the United States Patent Office. Much material is included which will confuse the novice and needlessly waste the time of the better informed.

Another theory or method of writing on technical subjects is for the author to "Test all things and hold fast to that which is good," in other words, to exercise an editorial function, which he is supposed to be competent to do, of the subject whereof he writes and thus save the reader, who is presumably less well informed than the author, from wasting his time with the bizarre word play of patent lawyers and the often curious imaginings of those who make inventing an indoor sport. However, Ellis and Meigs are perhaps justified in refraining from the exercise of the edi-

torial function since the art of producing gasoline from the higher boiling oils, which is the principal theme of their book, is still in an unsettled condition. Just a few days before the writing of this review, the Burton process, evidently the most successful of any of the processes which have had fair large scale trial, was reported in the press to have caused the death of seven men and the serious burning of about forty others in an explosion at Whiting, Ind. It is, therefore, well to keep in mind that the manufacture of gasoline from higher boiling hydrocarbons is a comparatively new art and that five or ten years from now the best process may be one which has not yet had fair large scale trial. However, it is doubtful if any one will be helped by rather lengthy descriptions of processes, such as the following, to which six full pages are devoted and the character of which may be judged from the following excerpts:

It is asserted that by heating oils which, like many crude petroleum and residua, consist largely of carbon compounds containing from ten to twenty or more carbons in the molecule, with a suitable control of the conditions, a depolymerization of comparatively simple and regulable type and without complex side reactions can be produced. Under proper conditions, it is said, the oil is broken down mainly into gaseous compounds, having two carbon atoms, without deposition of carbon or formation of tar.

The oils best adapted are crude petroleum composed of oils containing hydrocarbons with more than ten carbons.

On exposing such high boiling hydrocarbons in vapor form to temperatures around 700 deg. C. (1,292 deg. F.) and within 50 to 75 deg. C. on either side of that point, a regularly gasifying depolymerization sets in with the production of low molecular gaseous hydrocarbons without any great amount of other synthetical or analytical side reactions as long as vapor of unchanged oil still remains in the sphere of action. Such vapor seems to have, it is stated, a shielding action on the products.

At 800 deg. C. (1,472 deg. F.) breaking down of ethylene, propylene, etc., is apt to begin. Another reason for the limit given is that with chambers of large section it is difficult to prevent stratification—a separation of oil vapors and gas. And a stratum of gas, free of oil vapors, is apt to suffer damage at temperatures which would otherwise be safe.

The composition of the products will vary somewhat with that of the original oil and with the details of operation.

Admixing the gas with air or oxygen and passing over catalyzers such as platinum or palladium, various useful oxidized products may be obtained and condensed or absorbed, leaving the ethane.

In recovering the olefins, instead of chilling the gas, it may be scrubbed with cold concentrated sulphuric acid which is claimed to have but little action upon the olefins proper. The acid solution upon dilution separates polymerized unsaturated aliphatic hydrocarbons.

BENJAMIN T. BROOKS.

FESTIGKEITSEIGENSCHAFTEN UND GEFUGE BILDER DER KONSTRUKTIONSMATERIALIEN—Von Dr.-Ing. C. Bach und R. Baumann, professoren an der Technischen Hochschule Stuttgart. Zweite, Stark Vermehrte Auflage. Berlin, Germany: Verlag von Julius Springer. Cloth; 8 x 10 in.; pp. 191; illustrated.

The rather unique German book noted above is an illustrated encyclopædia covering the strength of the metallic materials of construction. It presents graphs showing the relations between deformation and loading for a certain steel, for instance. Illustrations are printed alongside showing the typical test-bar, the surface of fracture and the normal microstructure. Many pictures are given of faulty structures and the nature of the breaks, both as seen by the eye and under the microscope. Carbon steels, plain and annealed, special alloy steels, cast iron and steel, malleable iron, brass, bronze, and the principal non-ferrous metals are covered in this manner in 950 illustrations. Apparently most of the material is original with the authors. Typographically the book is excellent, the micrographs being particularly well printed. It would be a good reference book for any control or testing laboratory, especially those working with ferrous metals.

E. E. THUM.

Synopsis of Recent Chemical & Metallurgical Literature

Sulphuric Acid During the War.—The story of the important rôle played by sulphuric acid in the World War is very clearly told in a paper by H. J. Bailey which was printed in the July 15, 1921, issue of the *Journal of the Society of Chemical Industry*. The stringent measures taken in Great Britain for conserving this acid and its principal raw materials are reviewed. Statistical data are presented showing the production and utilization of all acid produced in England during the period 1915-1918 and of the sources and consumption of pyrites, pyrites cinders, spent oxide and sulphur.

The chamber-acid plants of Great Britain reached their maximum output in March, 1917, when they were producing at the rate of 1,307,000 tons of 100 per cent sulphuric acid. In the following table the uses of the chamber acid during 1916, 1917, 1918 and five months of 1919 are summarized. The figures for the latter period show the transition toward normal peace-time practice.

SULPHURIC ACID FROM CHAMBER-PLANTS IN TERMS OF 100 PER CENT H_2SO_4

The relation of sulphuric acid to the fertilizer industries is given detailed study and statistical tables are included which show production and consumption of superphosphates, mixed fertilizers, basic slag and ammonium sulphate.

Solar Cooker on Mount Wilson.—In a very interesting report of Smithsonian Institution's Explorations for 1920, vol. 72, No. 6, of Smithsonian Miscellaneous Collections, Publication 2619, Washington, 1921, there is a record of a solar cooker designed by Dr. Abbott at the Mt. Wilson Observatory. In this device Mrs. Abbott, who had charge of the experiment, was able to bake excellent bread, cook meat dishes, vegetables and prepare fruits and vegetables for preserving. In short, all cooking operations were easily performed except frying. It consists in a parabolic cylindrical mirror with a polished aluminum surface of about 100 sq.ft. which focuses the sun's rays upon a blackened tube filled with mineral oil which in turn communicates with an iron reservoir of oil in which are two baking ovens. A continuous circulation of the heated oil keeps the ovens hot. It is said that Mrs. Abbott was much envied for her cool kitchen and novel appliance by the ladies of the mountain.

The solar cooker was constructed on Dr. Abbott's plans, largely at the cost of grants for the American Academy of Arts and Science in Boston and the National Academy of Sciences. It has proved successful, although as yet it is somewhat of a luxury and is available for relatively cloudless regions rather than as a generally useful appliance. The device is very simple, the oil pipe being fixed above the mirror, which by a simple clockwork device may be made to follow the sun. The idea suggests itself that the apparatus might well be used as a pre-heater on bright days to the saving of considerable coal. It might also be used in tropical countries for drying fruits and for the preparation of copra. Again, it might be that a kitchen of this sort could be provided with a hearth for artificial heat to be used on cloudy days but with sun heat availed of on days that are bright.

Leather Industry in India.—A recent summary of conditions in the leather industry of India is contained in an article by Sir Henry Ledgard, which was published in the May, 1921, issue of the *Journal of Indian Industries and Labour*. According to this report "there exists in southern India and the Bombay Presidency a great number of tanneries, chiefly small but in the aggregate producing a great quantity of leather (mainly from cow hides and those not fully tanned), also a large number of tanned goat and sheep skins, most of the leather being exported to the United Kingdom. Little or no machinery is used in these tanneries at present. This trade is passing through a period of depression. In the Punjab there are seven or eight tanneries, in most cases designed to tan buffalo and cow hides and skins. At present they are producing much below their capacity, and chiefly buffalo leather; very little machinery is used and the leather is not fully tanned or set out, or rolled to render it solid and wear-resisting as good sole leather should be. This leather finds a market in most towns in northern India in the manufacture of the cheap bazar-made boots and shoes, also in repairing and resoling work. It could be made more valuable if machinery were applied to its preparation."

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Alloy for High-Temperature Uses.—The need in many metallurgical and chemical operations for an alloy which will withstand exposure to high temperatures without material oxidation or disintegration has prompted the development by Frank A. Fahrenwald, of Cleveland Heights, Ohio, of an alloy which is claimed to be sufficiently resistant for most practical purposes. The alloy consists substantially of 75 to 85 per cent of iron, 10 to 20 per cent of chromium, 2 to 6 per cent of silicon, 0.5 to 1 per cent of each of the metals manganese and titanium, and 0.2 to 2 per cent of carbon. (1,378,941; May 24, 1921.)

Alloys With Degasifying and Deoxidizing Properties.—Patents numbered 1,382,146 and 1,382,147 and issued to Calvin Vos, of New York, describe certain alloys, which because of special degasifying and deoxidizing properties are claimed to be of value in the manufacture of steel. These alloys consist of aluminum within the limits of from 90 to 95 per cent, magnesium within the limits of from 2 to 10 per cent, ferrosilicon within the limits of from 0.02 to 3 per cent and either uranium oxide or zirconium within the limits of from 0.01 to 6 per cent. Sodium fluoride is used as a flux. (June 21, 1921.)

Preparation of Glacial Acetic Acid.—Roland L. Andreau, assignor to E. I. du Pont de Nemours & Co. of Wilmington, Del., has described a process for preparing substantially anhydrous organic acids which is especially applicable to glacial acetic acid. In this process he is able to use sulphuric acid of 100 per cent strength without obtaining the usual decomposing and charring of the acetic acid formed. Briefly stated, the invention consists of carrying on the reaction between anhydrous sodium acetate and the sulphuric acid in the presence of a non-volatile and inert liquid such as paraffin. A double decomposition takes place very smoothly with the formation of substantially anhydrous acetic acid and of sodium sulphate, which remains in suspension in the oil in a finely divided state. There being no caking, the acetic acid is distilled over immediately. The distillate is of about 95 per cent strength or better. (1,381,782; June 14, 1921.)

Process of Producing Phthaleins.—The usual condensation of phthalic anhydride with a phenol for the production of a phthalein—e.g., phenolphthalein—occurs only in the presence of some dehydrating agent such as concentrated sulphuric acid. Most of these condensing agents have the disadvantage of forming tarry byproducts which interfere with the refining of the final product besides giving a yield of only 30 to 60 per cent of the theoretical. A process which has recently been patented substitutes an anhydrous sulphonic acid or a mixture containing such an acid for the usual condensing agent. It is claimed that a yield equivalent to 90 per cent of the theoretical can be obtained in this manner. (1,381,503; Alfred L. Rispler, assignor to Monsanto Chemical Works of St. Louis, Mo.; June 14, 1921.)

A Basic Sodium Naphtholate.—As a substitute for solid sodium naphtholate in the preparation of naphthol-carboxylic acids, L. F. Chebotaref, a Russian citizen residing in Wappinger Falls, New York, proposes a new substance, which he characterizes as a basic alkali naphtholate. In the case of the sodium salt this is prepared by fusing 15 parts of sodium naphthalene-beta-sulphonate with 11 parts of caustic soda for 2 hours at a temperature not higher than 350 deg. C. The sodium sulphite formed precipitates into the bottom layer; the upper layer when decanted and allowed to cool will congeal into a yellow

crystalline solid, easily soluble in both water and alcohol. Its composition corresponds empirically to $C_{10}H_8O_2Na_2$ and in properties it compares with a substance represented by an addition product of 1 mol of sodium naphtholate and 1 mol of caustic soda. (1,381,280, assigned, by mesne assignments, to National Aniline & Chemical Co., Inc. June 14, 1921.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Treatment of Nitrous Gases.—In the absorption of dilute nitrous gases by means of solid absorption agents, and the decomposition of the resulting product to produce concentrated nitrous oxides and nitric acid, the combined process is conducted in retort-like, acid- and fire-proof vessels surrounded by gas-tight jackets capable of resisting comparatively high pressures. The hot gases before actually entering the retorts pass into the space between the jacket and the retort in order to heat the latter and thus enable either absorption or decomposition to take place. The absorbent may be such as is described in specification 137,071, consisting of a mixture of a dry base with one or more metallic oxides and the absorption is advantageously effected at 300-600 deg. C. In one form of the apparatus shown in the

figure, the furnace gases first pass to the vessel C containing material fully saturated with nitrous gases through the valve B, but before entering the inner retort traverse the interstices between the jacket and the retort. To facilitate the decomposition, which is preferably effected at a pressure below that of the absorption, a small portion of the furnace gases is led through the valve D actually into the retort and carries with it the concentrated nitrous gases and nitric acid to the exit F. The greater portion of the furnace gases leaves the vessel C by the valve G and enters the second vessel H containing fresh or denitrated material, after passing through the space between the retort and the jacket. The residual gases freed from nitrous gases escape through the valve I and pipe L. When the material in the vessel H becomes saturated, the circulation of gases is reversed—i.e., the furnace gases enter the vessel H and then pass on to C. The valve D may be shut off entirely, the necessary gases then entering the retort through holes in the retort walls. Alternatively the retort walls may be made porous. Instead of two vessels, a battery connected on the counter-current principle or in any suitable manner may be employed. (Br. Pat. 163,026; not yet accepted. Norsk Hydro-Elektrisk Kvaelfstofaktieselskab, Christiania; June 29, 1921.)

Alloy for Permanent Magnets.—Steel alloys suitable for permanent magnets and other purposes are made by alloying with carbon steel, containing about 0.25 to 1.5 per cent of carbon, about 5 to 19 per cent of cobalt. Tungsten (or vanadium or molybdenum) or chromium, nickel and tungsten (or vanadium or molybdenum) may also be added, and also up to about 1 per cent of manganese. The tungsten may vary up to about 10 per cent and the nickel and chromium up to about 5 per cent each. Cast ingots of the alloys may be heated to about 1,000 deg. C., forged, hardened at about 850 or 900 deg. C., and magnetized. (Br. Pat. 164,039. Sir R. A. Hadfield, Westminster, July 20, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Program, American Chemical Society Meeting

The final program for the sixty-second meeting of the American Chemical Society, New York, Sept. 6 to 10, is as follows:

TUESDAY, SEPT. 6

- 9 a.m.—Registration begins at the Chemists' Club, 52 East 41st St.
 3 p.m.—Council meeting at the Chemists' Club.
 6:30 p.m.—Dinner to the Council at the Chemists' Club.
 9 p.m.—Adjourned meeting of Council, if necessary.

WEDNESDAY, SEPT. 7

- 9:30 a.m.—General meeting, Columbia University gymnasium:
 Address of Welcome, John E. Teeple, chairman, New York Section.
 Response, Edgar F. Smith, president, American Chemical Society.
 "Chemistry and the State," Francis P. Garvan, president, Chemical Foundation.
 "Mustard Gas," Sir William J. Pope.
 "Organization of Industrial Research in Canada," Prof. R. F. Ruttan.
 12:30 p.m.—Society of Chemical Industry Luncheon to British and Canadian visitors.
 2 p.m.—Divisional meetings at Columbia University.
 4 p.m.—Reception and lawn party given by Columbia University on the university green, 120th St. and Amsterdam Ave.
 8 p.m.—Smoker at Waldorf-Astoria.

THURSDAY, SEPT. 8

- 9:30 a.m.—Divisional meetings at Columbia University.
 2 p.m.—Organ recital by Prof. Samuel A. Baldwin in the Great Hall of the College of the City of New York, 139th St. and Convent Ave., followed by
 2:30 p.m.—International meeting:
 "Chemistry and Civilization," Dr. Edgar F. Smith.
 "Science and Civilization; the Rôle of Chemistry," by Prof. Charles Baskerville.
 "Energy; Its Sources and Future Possibilities," by Dr. Arthur D. Little.
 "The Engineer; Human and Superior Direction of Power," by Dr. Leo H. Baekeland.
 "Chemistry and Life," by Sir William J. Pope.
 "Theories and Their Development," by Dr. Willis R. Whitney.
 "Research Applied to the World's Work," by Dr. C. E. K. Mees.
 "Problem of Diffusion and Its Bearing on Civilization," by Prof. Ernst Cohen, of the University of Utrecht.
 "Catalysis; The New Economic Factor," by Prof. Wilder D. Bancroft.
 8 p.m.—Banquet at Waldorf-Astoria.

FRIDAY, SEPT. 9

- 9:30 a.m. and 2 p.m.—Divisional meetings at Columbia University.
 8 p.m.—Public meeting, Columbia University gymnasium:
 Presentation of Priestley portrait by C. A. Browne.
 President's address, "Progress in Chemistry," Edgar F. Smith.

SATURDAY, SEPT. 10

Visits to plants of the following concerns have been arranged by the committee: National Biscuit Co., Ladew Co., Ziegel Eiseman Co., American Tobacco Co., Standard Oil Co. of New York, Standard Oil Co. of New Jersey, Manhattan Rubber Co., Passaic Print and Dye Works, Seaboard Byproduct Coke Co., Liebmann's Brewery.

DIVISIONAL MEETINGS

The following divisions and sections will meet on the days noted:

- Division of Agricultural and Food Chemistry, Wednesday and Thursday, 16 papers to be presented.
 Section of Sugar Chemistry, Wednesday, Thursday and Friday, 24 papers.

Division of Dye Chemistry, Thursday and Friday, 21 papers.

Division of Organic Chemistry, Wednesday, Thursday and Friday, 41 papers.

Division of Biological Chemistry, Wednesday, Thursday and Friday, 40 papers, including a symposium on vitamins.

Division of Physical and Inorganic Chemistry, Wednesday, Thursday and Friday, 48 papers.

Section of Leather Chemistry, Wednesday, Thursday and Friday, 24 papers.

Section of Cellulose Chemistry, Wednesday and Thursday, 11 papers.

Division of Rubber Chemistry, Wednesday, Thursday and Friday, 21 papers.

Section of Chemical Education, Wednesday, Thursday and Friday, 10 papers.

Division of Industrial and Engineering Chemistry, Wednesday, Thursday and Friday, 35 papers, including symposia on filtration and on the chemistry of gases and fuel.

Division of Fertilizer Chemistry, Wednesday and Thursday, 23 papers.

Section of Petroleum Chemistry, Wednesday, Thursday and Friday, 12 papers, including symposium on emulsification problems.

Division of Water, Sewage and Sanitation, Friday, 7 papers.

Division of Chemistry of Medicinal Products, Friday, 13 papers.

Steel Treaters' Convention

An imposing list of seventy-eight papers has been secured for presentation and discussion at the forthcoming convention of the American Society for Steel Treating, held in conjunction with an exhibit of metallurgical equipment at Indianapolis, Sept. 19 to 24, 1921.

Tool steels will be discussed in nine papers by Messrs. Brown, Calkins, d'Arcambal, Green, Marshall, Medwedeff, Nelson, Seidell and Townsend.

Various problems in metallographic research will occupy six papers, by Messrs. Dowdell, Gill and Bowman, Hoffman, Lau, White and Helrigel.

Fourteen papers on general practice in heat-treatment will be presented by Messrs. Blacet, Cowdrey, Cope, Janitzky, Keller, Langstroth, Haywood, Hoyt and Bierman, Lynch, Merton, Priestley, Ward, White and Gaun, while there will be nineteen papers descriptive of new heat-treating furnaces or pieces of miscellaneous equipment.

Management will be discussed in ten papers, by Messrs. Bellis, Blue, Bressler, Langenburg, Pierce, Smart, Woodside, Wood, Millard and Medwedeff.

Properties of carbon and alloy steels will occupy Messrs. French, Grossman, Johnson, McCormick, Styri, Vannick, Bird, Cox, Johnson, Holz and Wild.

Labor Disputes and Wage Reductions in British Chemical Plants

The following developments were reported recently by cable from London:

The Minister of Labor has intervened in the dispute between the chemical companies and their employees and it is expected that representatives of the employers and the men's union will again confer. The dispute affects 30,000 men.

Ninety per cent of the employees of the Brunner-Mond Co. have promised their employers that they will not walk out, even if a general chemical strike is called. (It will be recalled that the company threatened to close down its Winnington works unless sufficient men accepted the reduced wage and agreed to continue at work under the new wage scale.)

A ballot taken by the Scottish shale miners shows that the men agree to a reduction in wages amounting to 3s. 2d. per day.

Decision on Standard of Comparison in Minerals Separation vs. Butte & Superior Suit

Decision was rendered of Friday, Aug 12, by Judge George M. Bourquin, in the Montana U. S. District Court, on the motion of plaintiffs that the court determine a standard of comparison for the guidance of the master in the settlement to be made by the Butte & Superior Mining Co. to Minerals Separation, Ltd., et. al., for infringement upon patents.

Judge Bourquin's decision follows:

Plaintiffs' patent valid and defendant having infringed it (250 U. S., 336), the suit is in the final stage and has been referred to a master to take and state an account.

Therein plaintiffs move the court to determine a standard of comparison for the guidance of the master. The standard they contend for is processes known (1) at the date of patent, or (2) at the date infringement began.

Defendant resists specific and particular instructions to the master as calculated to embarrass the proceedings by vague determinations in respect to evidence before tendered, and maintains the proper standard is processes known at any time so far as subsequent infringement is concerned. The issue of relativity in time of standard and infringement has been exhaustively argued and briefed, and some time to be decided, better be decided now. There is no controlling decision in this circuit, the issue not having been expressly raised and determined in either Supreme Court or Circuit Court of Appeals. In several cases the Supreme Court's language is that the infringer accounts for the fruits of the advantage which he derived from the use of that invention, over what he would have had in using other means then open to the public and adequate to enable him to obtain an equally beneficial result.

The rule of comparison is settled law, and contemplates that the infringer had a choice of processes, chose that of the patent, and gained an advantage over what would have been his had he chosen otherwise. Obviously his choice is made from processes existing at the time of choice, that is, at the time infringement from day to day and as alternative presents itself. He is not limited in fact to the process of the patent and processes existing only at the date of the patent, and the principle of standards does not require nor sanction that he be so limited in theory. For the advantage he actually gains, and which as profits or savings he must render to the patentee, is only that of the invention over other processes he might have chosen in lieu of the invention and did not.

What the infringer thus gains is also what the patentee is presumed to thus lose, so far as accounting for profits is concerned, and equity is done when all such gains are taken from the infringer and given to the patentee; for thus the former loses nothing, he is not penalized, the latter is made whole, and he is not given gratuities nor rewarded beyond his present deserts, as otherwise would be the case. And it seems fairly clear that this is the import of the quoted language of the Supreme Court.

The event to which the court refers is the infringement, and the time to which it refers is "then" at that time, the time of the antecedent event.

In so far as the motion seeks a general and not a particular determination, it is granted. The standard of comparison that will govern the master is any standard (having in mind the distinction between processes and standard) that is duly made to appear, in respect to subsequent infringement.

Australian National Research Council Holds First Meeting

Sir Edgeworth David, first president of the Australian National Research Council, which opened its first session at Melbourne, Aug. 24, declared it was necessary to establish the basic chemical industries in Australia and to work for co-ordination generally, throughout the Commonwealth, of scientific effort.

New British Act Affects Chemical Imports

On Aug. 25 the Board of Trade announced that part 1 of the safeguarding of industries act, dealing with all synthetic and organic chemicals, would come into full operation on Oct. 1. All goods arriving in England on or after that date will be liable to duty regardless of the date when the goods were ordered.

American Ceramic Society at the Chemical Exposition

The American Ceramic Society will be represented at the Seventh National Exposition of Chemical Industries, booth 451. A larger booth than usual has been obtained this year in order that this may form a real headquarters for members at the exposition whether they be visitors or exhibitors. Small committee meetings may be held and appointments made to meet friends. Every member who plans to attend the exposition is asked to register at the booth and use it as his personal headquarters.

Friday, Sept. 16, will be Ceramic Day. In the afternoon a program along ceramic and chemical lines will be given by interesting speakers. In the evening motion picture films on the industry will be shown.

On Thursday and Saturday, Sept. 15 and 17, at 9:30 a.m., a conference will be held at the Hotel Commodore, including the board of trustees, officers of divisions and sections and members of the committees with ex-presidents. This conference has been called by President Pence so that the officers in each group in the organization can counsel together, formulate a general program of activities for the entire society, and discuss methods and policies. Efficiency and methods, definiteness and attractiveness of program, activity and persistency of directing officers and extent to which the individual members in each of the divisions and sections are kept informed and interested will be taken up.

Some of the divisions are growing in numbers and influence, while others are struggling for existence. Some of the standing committees have accomplished a great deal, while others do not know how to get started. Some of the local sections flourish, while others struggle along in indifference. Some of the divisions have co-operative working relations with other technical organizations and with industrial associations, while others have none.

The officers of each division, section and committee are urged to prepare for presentation at this meeting a statement of their activities, present and past, an exhibit of all printed notices and circular letters used at any time; and each division is asked to send at once to Ross C. Purdy, the new organizing secretary, a list of all industrial associations, together with names and addresses of officers, which, directly or indirectly, are or could be interested in the work of the American Ceramic Society. The society is also anxious to receive a list of addresses of all trade, industrial or technical journals and house organs, no matter how remote their interest might be, to which notices of the activities of the American Ceramic Society can be sent. The organizing secretary wants to learn of ways and means of assisting each group in the organization and is interested that everyone should be present at the conference to be opened on Sept. 15.

Annual Meeting of the Societe de Chimie Industrielle de France, October, 1921

The annual meeting of the Société de Chimie Industrielle de France will take place Oct. 9 to 12, 1921, in Paris. The following sections will be represented: Analytical Chemistry; Plant Machinery; Laboratory Apparatus; Gas and Coke Industries; Hydrocarbons, Petroleum; Wood Distribution; Refrigerating Industries; Water; Metallurgy and Electrometallurgy; Precious Metals; Heavy Chemicals; Fine Chemicals; Electrochemistry; Glass, Ceramics and Enameling; Rare Earths, Radio-active Bodies; Pharmaceutical Products; Photographic Products; Powder and Explosives; Essences, Natural and Synthetic Perfumes; Resins, Paints, Lacquers and Varnishes; Rubber and Substitutes; Fatty Materials, Soap, Candles, Glycerine, Cellulose, Paper; Plastic Materials, Artificial Textiles; Bleaching, Dyeing, Printing; Tanning; Fermentation; Sugar; Starch; Milk; Food Products; Agricultural Chemistry, Soils and Fertilizers.

An exposition of the chemical industry, Oct. 7 to 16, will feature this first annual meeting of the society.

Fertilizer Statistics

The National Fertilizer Association is co-operating with the Bureau of the Census in an effort to collect complete statistics on the production of acid phosphate and sulphuric acid.

Temporary Dye Control Extended

No real opposition was encountered in the Senate to the proposal to continue until after the recess the temporary control of imports of dyes. The subject came in for extended discussion, but there was no disposition on the part of any Senator to allow the measure to lapse entirely. Advantage was taken of the opportunity to denounce a permanent embargo. Senator Hitchcock attempted to establish that the War Trade Board, in handling the temporary embargo, had made it almost impossible for an American user to get imports of a dye in time to use it, even when it was not obtainable in the United States. Senator Smoot, in urging the passage of the extension of the control, among other things said:

I am opposed to an embargo on dyestuffs or any other article of common use. I am for the extension of the temporary embargo, for the reason I wish to be fair with the dye manufacturers of the country. I believe we can give ample protection to the dye industry by the regular rates that may be inserted in the tariff bill.

I am investigating conditions of every dye that is manufactured. I am taking the manufacturer's number of that dye. I am trying to find its cost abroad, at least the price for which it is sold when imported into this country and into foreign countries, both before the war and today. I am investigating the American value of those dyes, where they are made in this country. I cannot say today what rate of duty will be necessary. I do know, however, that in my investigation so far there must be two classes of dyes, if not three, and in those classes there will be a great difference in rates.

Senator Pomerene, of Ohio, stated to the Senate that imports of dyes in 1920 aggregated \$5,000,000 in value. During that year dyes to the value of \$29,000,000 were exported. This led Senator Smoot to say that 90 per cent of the exports consisted of a few articles, particularly synthetic indigo and sulphur black. He said that sulphur black has been made in this country for thirty years and that we can compete with nearly every country so far as that dye is concerned. We will not be able to compete with Germany in the manufacture of synthetic indigo, he declared, and just as soon as Germany gets back to quantity production of synthetic indigo that country will take all the markets outside the United States, he said.

In the course of the debate Senator McCumber, an influential member of the Finance Committee, made this significant remark: "Before we get through with the tariff bill, I think we shall have succeeded in getting a measure that will be sufficiently protective without an embargo."

While the general impression in Washington at the time of this writing is that the Senate committee will decline to restore the dye embargo to the tariff bill no decision has been reached and it is very evident that several members of the committee who are not particularly impressed with the embargo policy hesitate to accept responsibility for killing it.

Obituary

PETER COOPER HEWITT, electrical and mechanical inventor and engineer, died in the American Hospital in Paris, Aug. 25. He was born in New York on March 5, 1861, and was educated at the Stevens Institute of Technology and the Columbia University School of Mines. One of his earliest inventions was that of improved machinery in his grandfather's famous glue factory. His greatest success was achieved in the field of electricity—the Cooper Hewitt lamp, the Cooper Hewitt rectifier and other inventions bringing international fame. Because of his scientific attainments, Mr. Hewitt was made first vice-president of the United States Naval Consulting Board during the war and in that capacity he did much valuable patriotic service.

ROSS F. MACMICHAEL, of the United States Gypsum Co., Chicago, was drowned in Lake Michigan on July 10. Born

in 1885, he was educated through private study. After occupying various minor positions he became field engineer for the American Smelters Securities Co. at Asarco, Durango, Mexico. Later he became associated with the Northern Clay Co., Auburn, Wash., carrying on technical problems in chemical engineering. Returning to the American Smelting & Refining Co. at Hayden, Ariz., as construction and experimental engineer, he invented the MacMichael chimney gas tester and the MacMichael viscosimeter. He had just come to Chicago to engage in the design of special machinery for the United States Gypsum Co. He was a member of the American Ceramic Society and the American Association of Engineers.

Dr. FRANK N. SMALLEY, chief chemist of the Southern Cotton Oil Co., died on Aug. 15 at the Homeopathic Hospital, Boston. Death was due to peritonitis, which set in following an operation. Dr. Smalley was born in Westborough, Mass., in 1874. He received his education in Massachusetts and was graduated from the Massachusetts Institute of Technology in 1898. A month later his services were secured by the Southern Cotton Oil Co., and he went to Savannah to enter its employ as one of its chemists. Some years ago he was given full charge as chief chemist for all of the laboratories of the company. Well known and highly esteemed in the cotton oil industry, his research work in his field caused his alma mater to confer on him the degree of doctor of philosophy. Dr. Smalley led an active life and had wide interests. He served as a non-commissioned officer in the United States Army shortly after the Spanish-American War and saw service in the Philippines. He was a member of the Society of Chemical Industry, the American Oil Chemists Society, the American Chemical Society and the American Institute of Chemical Engineers.

GEORGE W. THOMAS, president of R. Thomas & Sons Co., manufacturer of electric porcelain, died recently at his home at East Liverpool, Ohio, at the age of sixty-nine. He was the pioneer producer of high-voltage porcelain in the United States.

Personal

Dr. HOWARD ADLER has recently been made assistant professor of the department of chemistry of the University of Chicago and will also succeed Gerald L. Wendt as managing editor of the *Chemical Bulletin*, organ of the Western Sections of the American Chemical Society.

HOWARD W. AMBRUSTER, formerly general manager of Hemingway & Co., of Bound Brook, N. J., announces that he has opened his own office at 261 Broadway, New York City, for the purchase or sale of chemicals or colors.

R. R. DANIELSON, U. S. Bureau of Standards, Washington, D. C., is making an extended business visit in Chicago.

BURTON DUNGLINSON, formerly with the American Chemical & Sugar Machinery Co., is going to London to represent the Republic Flow Meters Co. of Chicago in the European field.

HERBERT A. HAUPTLI, superintendent of the Sears-Roebuck wall paper and dye plant, Chicago, Ill., is leaving for an extended trip to Europe to investigate methods of manufacture of wall paper, inks and dyestuffs.

J. T. SLEEPER, formerly manager of Ricketts & Co., Inc., and later research analyst for the Testing Laboratories of New York, has resigned from the latter position.

GEORGE OTIS SMITH, director of the United States Geological Survey, returned to Washington last week from London. The primary object of his visit to England was to serve as a member of the organization committee of the International Geological Congress, the next meeting of which is being arranged for August, 1922, at Brussels.

CLYDE E. WILLIAMS has been appointed superintendent of the U. S. Bureau of Mines Experiment Station at Seattle, Wash.

Current Market Reports

Chemical and Allied Industrial Markets

NEW YORK, Sept. 5, 1921.

Very encouraging reports were noted from the heavy chemical trade during the past week. Business seems to be showing a decided improvement and efforts to make this condition permanent are being made throughout the trade. Miscellaneous inquiries for small lots have increased and some sellers have placed considerable business. The volume of business is averaging better than it did a month ago, which is quite a favorable feature to record during the hot vacation period. Importing continues freely and importers find no difficulty in bringing in stocks of most materials at prices ruinous to domestic makers. The final settlement of the tariff question is expected to counter-balance this feature in a large way. Prices in general are fairly steady and are losing their recent softness. In many cases imported materials figure largely, but for the moment importers are holding their prices steady. Paper factories and textile mills have bought freely in certain commodities and inquiries from tanneries and dyers are on the increase. Shoe factories and enamelers are buying with a much better spirit and in larger quantities.

EXPORT SITUATION DISCOURAGING

The most discouraging feature at present is our export trade. Aside from the credit situation, foreign interests are underselling American producers in South America and other countries. Germany seems fully determined to win back her former commercial supremacy, regardless of what it costs. It seems problematical how far Germany can go on this price question, but it is the cause of no little concern to American interests which are not in a position to meet the keenest kind of competition. There were a few who expected a sharp decline in caustic soda. The resisting power and the gradual recovery of prices, however, speaks well for the underlying fundamental position of this chemical. Soda ash has also shown renewed strength and efforts to force the price down have not met with much success. It may be stated in general that the peak of the depression is passing and indications point to a steady improvement.

Advices from steel quarters indicate positive betterment. The decrease in the number of idle freight cars during July in spite of the fact that the greater part of the perishable freight had been moved before the end of the period has amounted to nearly one-third of their number. This fact alone has given a feeling of optimism to both consumer and manufacturers which will go a long way toward bringing better business, and its effects are already seen in the present improvement.

CHEMICALS

Buyers are calling for small lots of *bichromate of potash* and sales are reported at 11½c. per lb. There has been no apparent pressure in the market, but supplies seem sufficient to meet the current extent of inquiries. *Ammonium sulphate* has shown a noteworthy increase among the export and also domestic trade. Business has been very active and prices are named at \$2.40@2.50 per 100 lb. in double bags for steamer New York. Out-of-town soap-makers have taken large quantities of *caustic potash* at lately prevailing prices and reports are heard that the situation is becoming tighter abroad. While some dealers quote 4½c. per lb. for imported 88-92 per cent, other large jobbers are asking above this figure and state that sales have gone through at 4½c. per lb. Producers of *acetate of soda* are asking 4½c. per lb. for this chemical, but would undoubtedly accept 4c. on a firm offer, as recent sales have gone through at this figure. The movement is slow and devoid of particular feature. Trading in small lots of *bichromate of soda* is the best that can be reported at

present. Transactions up to 5 casks are going through at 7½c. per lb., with this figure named by most dealers. Offerings on spot are moderate and the tone is steady. Miscellaneous *caustic soda* inquiries are reaching the market in better volume. It is true that business is only moderately active, but the increased interest displayed seems to forecast expansion in trade in the very near future. It is difficult to place any European business on account of the strong competition existing. There are reports that some foreign producers have advanced their prices. Some South American business is going through and conditions at some points have improved materially. Spot sales are reported by dealers at \$3.85@3.90 per 100 lb. for standard brands. A few odd lots might be purchased at \$3.80. No change from the former selling price of 7½c. per lb. can be reported for *chlorate of soda*. Business is confined to prompt shipments and the volume for domestic use is quite satisfactory. Small lots of *nitrite of soda* have sold at prices ranging from 7@7½c. per lb. on spot, depending upon size of order. It is possible that a slight concession might be granted on a round quantity, although holders of these lots seem to be somewhat tighter in their ideas. Spot prices for *prussiate of soda* are holding steady for the imported and it is doubtful if better than 12c. per lb. could be done in the open market at present. Dealers quote 12@12½c. and report a fair consuming demand for small quantities. The withdrawal of one of the largest low-priced sellers of *bleaching powder* on account of the disposal of output has put the market on a higher trading level. Producers are quoting 2½c. per lb. for large drums at the works and it is doubtful if second hands could shade this figure on any sizeable quantities. Paper mills have placed orders for considerable quantities during the past few weeks. Small drums are quoted at 2½c. per lb. lot works. Spot prime material in large drums is quoted at \$2.85 per 100 lb., ex-store.

Importers of *oxalic acid* report sales at 16c. per lb. Brokers claim to be able to shade this price to 15½c. on odd lots, but dealers quote all the way up to 18c. for the domestic variety. Sales at the works are reported at 16c. per lb. Small-lot trading continues to feature the market. Sales of *zinc carbonate* are reported at 16c. per lb. by producers. On round lots a slight concession might be allowed. The present inquiry seems to be confined practically to small lots. Spot *zinc sulphate* is quoted at 3c. per lb., with occasional sales at \$2.90 per 100 lb. The latter figure is considered an inside price for large-quantity orders. Moderate inquiries are reported from the paint and textile industries. Sales of imported crystal *tartaric acid* have been made at 26¼@27½c. per lb., the prevailing quotation at the close being 27@28c. per lb., according to quantity and seller.

COAL-TAR PRODUCTS

There have been quite a number of orders in the market for quantity lots of intermediates during the past week and in some directions this is taken as an indication of decided improvement. There are some who believe, however, that the recent orders are coming from those who have depleted their stocks which they took on some months ago and that they will not be in the market again for several months to come. In any case the outlook is considerably better, as indications point to improved consuming demand. The uncertainty of the tariff remains a ruling cause for slowness in the market, aside from the long-continued persistency of consumers in staying out of the market. Plants generally are barely moving and many are completely shut down. No large sales of crude material were made during the past week. Intermediates are moving slowly and manufactures are holding their quotations fairly firm, except where sharp competition is noted, as in the cases of *beta naphthol* and *aniline oil*. Resale stocks are greatly reduced on most items. There are only a scant few where prices are declining on account of accumulated resale material on hand. Producers of *benzene* quote 27@33c. per gal., but cannot supply any spot material. In order to take care of the c.p. demand it has become necessary for first hands to notify fuel oil consumers

that they can expect a curtailment of supplies on all new contracts. The greater number of coke ovens are shut down with no signs of any improvement at present. The market on *naphthalene* continues very quiet, with the demand at a virtual standstill. Refiners' prices remain unchanged at 8½@9½c. per lb. for flake, but, resellers are willing to sell even below their quoted figure of 6¾c. per lb. for quantity business. Resale Government *phenol* is to be had at 9@11c. per lb., according to packing and quantity. Government surplus stocks are still offered at 12@15c. per lb. Refiners of natural *phenol* are quoting 15@16c. per lb. for their product.

Business has been going on in routine proportions with the pharmaceutical trade. Resale lots of *beta naphthol* are to be had in good quantity at 32c. per lb. and reports are heard that makers are willing to do 34c., although they still deny it. Competition is keen and prices have been slightly shaded on round lots. The demand is somewhat slow. Makers of *aniline oil* have brought their prices well into line and are now quoting 20c. per lb., although some are still shading higher prices to this level. Resale lots are to be had in good quantity as low as 18c. per lb. Little interest is being displayed by consumers. Producers of *alpha naphthylamine* are quoting lower prices at 35c@37c. per lb. There is very little *alpha* offered by resellers in the spot market, as makers have retained control of stocks. Manufacturers of *dimethylaniline* are quoting 45@50c. per lb. according to brand and are pretty well in line within this range. Reports are current that sales have been made by producers as low as 42c. per lb., and while this seems possible no maker is willing to admit it. Makers' prices for *paranitraniline* rule at 79@82c. per lb., with resale material below this level in very light supply. The demand is rather slow. Producers of *paratoluidine* have brought their prices into better alignment and are now quoting \$1.25@\$1.28 per lb. Demand for small lots only has been noted.

WAXES

There was a moderate inquiry for crude *beeswax*, but the situation underwent no important change. Crude African held around 15@16c. per lb., according to quantity and seller, with the Brazilian at 22@25c. per lb. Pure white closed nominally at 36@42c. per lb. While offerings of *candelilla wax* were not pressing on the market, lack of demand caused prices to hold on the recently reduced basis of 25@26c. per lb. Interest in *carnauba wax* centered in the lower grades, although domestic consumers refused to anticipate their wants and business reported was only of a hand-to-mouth nature, confined almost entirely to small lots. No. 2 North Country held at 25c. per lb. with the No. 3 North Country at 15c. No. 3 chalky settled nominally at 15½c. per lb. Spot offerings of *Japan wax* were firmly held and at the close the market ranged from 19½@20½c. per lb., depending on seller and quantity. Strength at primary centers was the supporting feature. The market for *paraffine* was unsettled, with liberal offerings by large producing interests. The export demand has shown only a slight improvement and competition for pending business has been very keen with the result that price shading continues. Crude scale of 122@124 deg. melting point was available in carlots for immediate shipment at 1¾c. per lb.

The St. Louis Market

ST. LOUIS, Sept. 2, 1921.

In spite of the fact that the month of August has always been looked upon as a dull period for the chemical market, there have been many favorable reports coming in from manufacturers stating that business has increased to a great extent over the past months, and all are very optimistic as to what the future holds. It is the general opinion that there is a tendency for prices to harden, as the majority of the items, especially the major ones, have reached the level where they are consistent with manufacturing cost. The above facts not only cover the drugs, pharmaceuticals and fine chemical lines, but also affect the heavy chemicals, where the demand has increased steadily and has strengthened the market considerably. Not only have declines been halted but in several instances

an upward change has been recorded. It is still true that buyers are very conservative in procuring their supplies and orders are not of large volume, but they are more numerous and frequent and in most instances are placed for immediate shipment. On some of the commodities the foreign material continues to be a disturbing element to the manufacturers. However, they are gradually becoming extinct.

ALKALIS

Caustic soda demand is good and manufacturers' schedules strictly adhered to. Price has advanced to \$4.25 per 100 lb. carload flat 76 deg. solid f.o.b. point of production. Further increases are not unexpected. *Soda ash* demand is fair with prices remaining the same—that is, \$2.66@ \$2.75 per 100 lb. in less than carload lots. *Bicarbonate of soda* demand is poor, with the price \$2 per 100 lb. for barrels or \$1.75 per 100 lb. for bags, carlots f.o.b. producers works.

CHEMICALS, DRUGS AND PHARMACEUTICALS

Acetanilid is very dull. We are now at the threshold of the preserving and canning season and a good volume of business should be transacted on *benzoate of soda* and *acid benzoic*, and furthermore this should be the opportune time to procure requirements, as the prices on these commodities have undoubtedly reached bottom, and with an increased demand will have a tendency to advance. There is nothing more than routine business on *ammonia water*, 26 deg., with prices firm. *Bismuth salts*, particularly subnitrate, is moving very lively. *Bromides* are weak. *Caffeine* has shown a very substantial increase the past thirty days. The heavy demand for *carbon bisulphide* which was evident the past several weeks still continues. However, it is not expected that this condition will prevail much longer, as the demand from agricultural sources will cease the next few weeks. *Chloroform* and *ether* are two commodities which should be classified as stable articles, as they have a regular source of outlet. Manufacturers have reduced their price of *codeine* and its salts. There is nothing startling to report on *cream of tartar* or *acid tartaric*. *Creosote* and *guaiacol* should shortly show an increase, as we are about to enter the season of the year when these articles will be in demand and liberal stocks should be carried. *Epsom salts* is being quoted in carlots at \$2.10 per 100 lb., f.o.b. factory, and less carlots at \$2.60 per 100 lb., f.o.b. St. Louis. *Glycerine* declined one-half cent and is now quoted at 14c. in drums, spot or contract. This is an exceptionally low price and the manufacturers are not pushing contracts at this figure. *Mercurials* are firm with steady flow of orders. *Morphine* and its salts have been reduced. *Saccharine* has taken a sudden spurt with many inquiries received and in most instances business resulting. *Salicylates* continue to move in a fair way, and an increased demand is expected very shortly, as the season for the salicylates is now approaching. Several weeks ago it was reported that there was a brisk demand for *silver nitrate* and this condition still prevails. *Sodium hyposulphite* continues in routine way. *Sulphur* is in good demand, with price at \$2.10 per 100 lb. for commercial in bags. The price of *zinc oxides* remains the same, with fairly good demand for the lead-free from the rubber trade. *Zinc sulphate* is ruling at 3½c. per lb. f.o.b. St. Louis.

ACIDS AND VEGETABLE OILS

Producers of commercial mineral acids are very much pleased with the present free movement of acids especially the *sulphuric* grade, which is moving in very large volume. Producers attribute the increase to the fact that many of the industrial plants which have been shut down for some months are beginning to operate. *Acid carboic* is very quiet. The demand for *citric acid* has been very disappointing and very little improvement can be expected at this time, as the soft drink season is about to close. The demand for *acid pyrogallie* shows no inclination to drop off and the inquiries and demand continue to increase. *Acid tannic* is moving in fair way.

The *castor oil* movement has really been very heavy the past month and price of 11½c. per lb. for returnable drums is very firm. *Linseed oil* has held firm at 78c. per gal.

basis raw in barrels ex-warehouse. The majority of the buyers are taking spot oil as they need it. *Turpentine* continues to advance and it holds strong at 65c. per gal. in barrels ex-warehouse.

PAINT MATERIALS

Lithopone and *barytes* are unchanged in price and the demand is still much under routine, the expected activity in the paint industry having as yet failed to materialize.

The Iron and Steel Market

PITTSBURGH, Sept. 2, 1921.

The volume of demand for steel products, taken as a whole, has continued to increase in the past fortnight, albeit the increases have been relatively small and not altogether steady. Sheets, bars and tubular goods show improvement most distinctly. Shapes, plates and rails stand at the foot of the list. Tin plate and wire products show demand that is governed by the season rather than by general business conditions. All steel mills show improvement in bookings, comparing July and August.

As improvement in demand has been most pronounced in the lighter steel products, naturally no large increase in steel production is shown. The rate of steel ingot production this week may be estimated as nearer 30 per cent than 25 per cent, and it is possible a full presentation would show a rate above 30 per cent. This compares with an average in July of about 21 per cent and a rate probably between 18 and 19 per cent at the middle of July, when the record low point was reached. Production of finished steel has increased slightly more than production of ingots, as here and there stocks of semi-finished steel or ingots are being drawn upon.

As for weeks past, the prominent fact in an analysis of the purchases of steel is that the buying is widespread in character, both geographically and by trades. All sections of the country are represented more or less in the improvement, but the Southern States show the best gain in proportion to the volume of business two or three months ago.

PRICES MUCH STEADIER

A survey of the course of prices since the first of the year shows how much steadier the steel market has become in the past thirty days. The end of last year brought an equalization in prices between the independents, which had largely advanced their prices, and the Steel Corporation, which held to the Industrial Board schedule of March 21, 1919. January saw a continuance of the equalized prices, while February witnessed an inception of price cutting by independents. A weighted average of the prominent finished steel products shows that from Feb. 1 to Aug. 1 there was a decline of fully \$15 per net ton, February and July each showing declines of more than \$5 a ton, while in August the weighted average dropped only 80c. a ton. It is barely possible that no further declines will be recorded, taking a broad view of the price situation.

PIG IRON AND COKE

Pig iron has been firming up in several districts in the past fortnight, and definite advances are recorded in the Buffalo, Chicago and valley markets. The trend in these cases is away from a market price that was below the cost of replacing the stock iron sold. On a general average, the freight assembly cost of ore, coke and limestone necessary to make a ton of pig iron is about \$10, against about \$5 before the war, and expectations are that the rates will be reduced by about 20 per cent. The freight rate reductions, however, have not occurred, and no one knows just when they will occur, while in some districts the stocks have been fairly well reduced, and here and there it is necessary for a furnace to resume operations. Naturally the furnace requires the buyer to pay its cost at least, when it has the recourse of not making iron. Liquidation of stocks was another matter.

The local market is quotable at \$20 for bessemer, \$19 for basic and \$20 for foundry iron f.o.b. valley furnaces, these quotations representing no change in bessemer and advances of \$1 on basic and 50c. on foundry. The common asking price on basic, however, is now \$20.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Flour Mills, 803 American Trust Bldg., have awarded a contract to Earl Cline, 1205 North 17th St., for the construction of its proposed new flour mill, 50 x 150 ft., to be equipped for a daily output of about 1,000 bbl. J. O. Walker is president.

Connecticut

BRIDGEPORT, CONN.—Arrangements are being perfected for a merger between the Raybestos Co., with local plant, and the General Asbestos & Rubber Co., Charleston, S. C., under the last noted name. Both companies specialize in the manufacture of textile asbestos products, including brake linings, etc., and the assets of the consolidated company will total \$9615,000. In addition to its Bridgeport works, the Raybestos Co. also maintains plants at Stratford, Conn., and Peterboro, Ont. The new company will continue the operation of these different factories. C. Bissell Jenkins will be chairman of the board of directors of the new organization, and Sumner Simpson, president.

Delaware

MILTON—The Edgewater Flour Mills have been acquired by Wilson & Hazzard. The new owners will make a number of improvements in the plant and place the mill in operation at an early date.

Florida

JACKSONVILLE—The Tidewater Glass Co., recently organized with a capital of \$1,150,000, has acquired local property for the erection of a new plant for the manufacture of commercial glassware products, as milk bottles, jars, etc., utilizing local sand in connection with production. Two plant units will be constructed at the present time, estimated to cost about \$300,000, with daily output of about two carloads of material. The equipment installation will include glass furnaces, tanks, annealing ovens, air compressors and other power equipment, mold shops, and with department for box manufacture. The new company is headed by C. H. Dankworth, Bellaire, O., and F. W. Stewart, Pittsburgh, Pa. Local offices are care of B. R. Kessler, secretary Jacksonville Chamber of Commerce, who has been instrumental in securing a site for the new company.

MIAMI—The Hector Supply Co. has acquired a local building, formerly used by the Southern Utilities Co., and will remodel the structure for a new plant for the manufacture of fertilizer products.

JACKSONVILLE—William W. Sheppard and Harry Whittier, both of Jacksonville, are organizing a new company, capitalized at \$3,000,000, for the establishment of a new oil-refining and gasoline plant. The initial capacity will be about 2,000 bbl. of crude oil and 20,000 gal. of gasoline per day.

TAMPA—The Southern Bottle Mfg. Co., recently organized with a capital of \$1,500,000, has completed plans for the erection of its proposed new local plant, to be 60 x 150 ft. Construction will be commenced at an early date. I. F. Jones is president and R. L. Rundell secretary.

Georgia

MONTICELLO—The Farmers' Milling Co., recently organized, is planning for the construction of a new flour mill on local site, with initial daily output of about 60 bbl.

COLUMBUS—The Armour Fertilizer Co., 209 West Jackson Blvd., Chicago, Ill., is reported to be planning for the rebuilding of its fertilizer works at Columbus, destroyed by fire, Aug. 9, with loss estimated at close to \$300,000.

Louisiana

NEW ORLEANS—The Louisiana Colotex Co. has commenced production at its new

local mill, recently completed at a cost of \$500,000. The plant will be devoted to the manufacture of special board products made from bagasse, the refuse from sugar cane. The new plant is the first of a number of such mills the company proposes to construct in different parts of the state.

Maryland

BALTIMORE—The Cooknut Corp., Lexington and Paca Sts., Baltimore, has completed plans for its proposed new 4-story plant on Canton St., 88 x 100 ft., for the manufacture of hard substitutes and kindred products. It is estimated to cost \$125,000. Erection will be commenced at an early date. W. R. Spruill is head.

WESTPORT—The Spanish American Cork Products Co., recently organized with a capital of \$500,000, is planning for the establishment of a large plant at Westportman, for the manufacture of cork products. The company is headed by Walter V. Harrison and Philip S. Ball. Westport.

BALTIMORE—The Maryland Vegetable Oil Co., recently organized with a capital of \$1,000,000, will take over an existing local plant, recently completed at a cost said to be over \$500,000, for the manufacture of refined cottonseed oil and other oil products. Operations will be commenced at an early date. Enos Stockbridge and Roland H. Brady, Baltimore, head the company.

Massachusetts

CHELSEA—Fire, Aug. 23, destroyed a portion of the plant of the United Indigo & Chemical Co., with loss estimated at about \$125,000.

HAVERHILL—The Bay State Brick & Stone Co., recently organized with a capital of \$200,000, has construction under way on a new plant on the local river front for the manufacture of brick; it is proposed to make the plant one of the largest in this section. The company has acquired the plant and property of the Auburn Brick Co., West Auburn, Mass., and will remove the equipment to the new Haverhill works. George L. Baldwin, formerly manager of the Auburn plant, is president.

Michigan

GRAND RAPIDS—The Cross-Kramer Oil Co., recently organized with a capital of \$50,000, and now operating an oil-compounding plant at Chicago, Ill., is considering the establishment of a similar plant at Grand Rapids. Richard A. Cross is president, and Fred W. Kramer secretary.

Missouri

CAPE GIRARDEAU—The National Silica Mining Co. is planning for the development and operation of silica properties in this section. Plans for the proposed plant are being prepared by G. E. Doane, consulting engineer, Poplar Bluff, Mo.

New Jersey

NEWARK—Matthew Walsh, Brooklyn, N. Y., manufacturer of leather belting, has leased a 3-story building at the rear of 28 Orange St., Newark, totalling about 6,000 sq. ft., for the establishment of a new belting factory.

PERKINTOWN—Fire, Aug. 24, caused by an explosion, destroyed the powder plant of the Columbia Salvage Co., adjoining the Delaware Ordnance Reserve Depot of the War Department. An official estimate of the loss has not been made.

CAMDEN—The Lutz Co., Thirty-first St. and Grays Ferry Ave., Philadelphia, Pa., manufacturer of castings, machinery, etc., has commenced the erection of a 1-story addition to its foundry, 80 x 120 ft., on Hayes Ave. William Lutz is president.

New York

BROOKLYN—The H. D. Roosen Co., 78 Twentieth St., manufacturer of inks, has filed plans for the erection of a new 1-story plant, 38 x 95 ft., at 67-87 Twenty-first St., to cost about \$16,000.

MECHANICSVILLE—Fire, Aug. 22, caused by a boiler explosion destroyed a portion of the plant of the West Virginia Pulp & Paper Co., including boiler department, equipped with a battery of three high-pressure boilers. The amount of estimated loss has not been announced.

NEW YORK—The Sinclair & Valentine Co., 21 St. Clair Pl., manufacturer of lithographing inks has commenced excavations for its proposed new 3-story plant on Broadway, between 125th and 130th Sts. The Lustbader Co., 423 Madison Ave., has the building contract.

TONAWANDA—The J. Spaulding & Sons Co., Wheeler St., manufacturer of fiber products, has construction under way on its new plant addition, consisting of a number of buildings estimated to cost about \$125,000. The company plans for early occupancy and will increase its present working force from 175 to about 400 operatives as soon as the extensions are ready for service.

Ohio

GARRETTSVILLE—The McWade Rubber Co. has broken ground for the erection of a 2-story plant addition, 48 x 130 ft. The P. L. Frank Construction Co., Garrettsville, has the building contract.

DAYTON—The Refiners Oil Co., 315 South Main St., has awarded a contract to Frank Hill Smith, Inc., Winters National Bank, for the erection of a new 1-story works building on South Ludlow St., 106 x 144 ft. to cost about \$40,000.

COVENTRY—The Palmer Match Co., ninth floor, Second National Bank Bldg., Akron, O., recently organized, has preliminary plans under way for the erection of its proposed new match-manufacturing plant at Coventry, near Kenmore, estimated to cost close to \$1,000,000. Charles H. Palmer is president.

Oklahoma

TULSA—The Producers & Refiners Corp., is planning for the construction of a new oil refinery on local site, to utilize crude oil from the Salt Creek field.

Pennsylvania

PITTSBURGH—The Standard Sanitary Mfg. Co., Ontario St. and Preble Ave., manufacturer of burned clay sanitary wares, has filed plans for the construction of a 1-story works addition to cost about \$15,000.

PHILADELPHIA—The General Smelting Co., Stock Exchange Bldg., has taken bids for the erection of a new 1-story plant at Bath and Westmoreland Sts. Emile G. Parrot, 328 South Broad St., is architect.

PHILADELPHIA—The Atlantic Refining Co., Passyunk Ave., is reported to have plans under way for the rebuilding of the portion of its local refinery, destroyed by fire Aug. 14, with loss estimated at close to \$1,000,000. The loss included a number of large tanks, 3 pumping plants, works buildings, etc.

Rhode Island

EAST GREENWICH—The Warwick Chemical Co., recently organized with a capital of \$50,000, is planning for the establishment of a local plant for the manufacture of dyes and affiliated products. The company is headed by Samuel A. Olevson, Arctic, R. I., and John J. Clarke, West Warwick, R. I.

South Carolina

PROSPERITY—The Prosperity Oil Mill Co. is considering plans for the construction of a new flour mill on a local site. Estimates of cost and details of equipment installation are being arranged.

West Virginia

NITRO—The Viscose Co. of America, Marcus Hook, Pa., has acquired a portion of the former powder works of the Government at Nitro, comprising Area E, totalling about 52 acres of land, with a number of large buildings. Three of the structures will be used by the new owner for the manufacture of pulp from cotton linters, to be utilized at its artificial silk mills at Marcus Hook and Roanoke, Va. Work has been commenced on an addition to this latter plant to cost about \$1,000,000.

Texas

WAXAHACHIE—The Texas Oil Products Co. has construction under way on a new local oil-refining plant, estimated to cost about \$750,000.

MEXIA—The Golden State Refining Co. has acquired a local site and plans for the erection of a new oil refinery with initial output of about 6,000 bbl. a day.

New Companies

THE NOBLE COLOR WORKS, INC., Brooklyn, N. Y., has been incorporated with a capital of \$25,000, to manufacture colors, paints, inks, etc. The incorporators are P. Conforti and V. Malvani. The company is represented by Collin, Wells & Hughes, 120 Broadway.

THE WESTERN METAL PRODUCTS CORP., Joliet, Ill., has been incorporated with a capital of \$50,000, to manufacture metal goods. The incorporators are Alan A. Bakewell, Walter B. Stewart and Frederick A. Hill, 314 Barber Bldg.

THE HENRYETTE GLASS & MFG. CO., Henryette, Okla., has been incorporated with a capital of \$50,000, to manufacture glass products. The incorporators are J. Balison and H. L. Chambers, Henryette.

BEETLE-BARNES-BAKER, INC., Lynn, Mass., has been incorporated with a capital of \$30,000, to manufacture waxes, rubber cement and kindred products. Lorenz F. Muther is president and William R. Beetle, 362 Massachusetts Ave., treasurer.

THE ASBESTOS MATERIALS CORP., New York, N. Y., has been incorporated with a capital of \$400,000, to manufacture asbestos products. The incorporators are H. L. Delatour, H. Kaufman and J. Steinbrink. The company is represented by M. Steinbrink, 215 Montague St., Brooklyn.

THE WRIGHTSMAN OIL CO., Jersey City, N. J., has been incorporated with a capital of 5,000 shares of stock, no par value, to manufacture refined oil products. The incorporators are Charles J. Skinner and John R. Turner. The company is represented by the Corporation Trust Co., 15 Exchange Pl.

THE ELITE CHEMICAL CO., Nashville, Tenn., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are E. B. Harper and Biscoe Griffith, Nashville.

THE CAMBRIDGE TANNING CO., Cambridge, Mass., has been incorporated with a capital of \$100,000, to manufacture leather products. Rishton T. Bailey, Massachusetts Ave. and Tannery St., is president and treasurer; Joseph J. Hurley is secretary.

THE VELVET SPECIALTY CO., 4708 Hastings St., Detroit, Mich., has been incorporated with a capital of \$25,000, to manufacture paints, oils, polishes, etc. The incorporators are Edward F. Callan, M. E. Jaynes and Thomas A. Jaynes, 5957 Stanton Ave.

THE SUPERIOR SMELTING & REFINING CO., Jersey City, N. J., has been organized under state laws to operate a metal smelting and refining plant. The company is headed by Godfrey A. Welter and Louis Friedman, 819 Jersey Ave.

THE FIBRE TIRE & RUBBER CO., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture fiber and rubber products of various kinds. The incorporators are M. N. Salamon, E. F. File and E. F. Stockle. The company is represented by C. Foley, 38 Park Row.

THE PRICE OIL CORP., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000, to manufacture refined petroleum products. The incorporators are Harry Hirsh, M. Kantor and C. A. Kleinman. The company is represented by Joseph Crail, Union Oil Bldg.

THE UNION RUBBER CO., Calais, Me., has been incorporated with a capital of \$500,000, to manufacture rubber products. Charlotte L. Lello, Calais, is president and treasurer; Harold H. Murchie is secretary.

THE FRANK MILLER CO., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture leather dressings, dyes and affiliated products. The incorporators are Frank C. Miller, S. G. Martin and G. V. Hart. The company is represented by E. A. Kenney, 120 Broadway.

THE INDUSTRIAL PETROLEUM CORP., 14 East Jackson Blvd., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture petroleum products. The incorporators are Samuel J. Lombard, Abner R. Allison and Thomas P. Collins.

FRASER & CO., Trenton, N. J., have been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The company is represented by Arthur W. Britton, 65 Cedar St., New York.

THE VERIBEST PRODUCTS, INC., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemicals, oils and kindred products. The incorporators are J. E. Morrell, L. F. Iverson and H. Grayer. The company is represented by J. C. Lewis, 247 Fifth Ave.

THE AVON MFG. CO., INC., Natick, Mass., has been incorporated with a capital of

\$25,000, to manufacture leather products. Lester F. Sargent is president and treasurer; Winfield Temple, High St., Westwood, Mass., is secretary.

THE PARAMOUNT DYESTUFF & CHEMICAL CO., Jersey City, N. J., has been incorporated with a capital of \$100,000, to manufacture chemicals, dyes and affiliated products. The incorporators are Maurice M. Reinhard, Francis J. Kremin and Maxwell Tischler. The company is represented by William M. Rysdyk, 76 Montgomery St.

THE NON TOX CHEMICAL CORP., Washington, D. C., has been incorporated under Delaware laws with a capital of \$300,000, to manufacture chemicals and chemical byproducts. The incorporators are Harry W. Bagby, Christie H. Fesler and Joseph J. Mawhinney, Washington. The company is represented by the Capitol Trust Co., Dover, Del.

THE B. ROBBINS CO., New York, N. Y., has been incorporated with a capital of \$12,000, to manufacture chemicals, chemical byproducts, etc. The incorporators are B. Robbins, H. D. Naum and J. Cohen. The company is represented by L. H. Robinson, 2 Rector St.

THE EXOLINE PRODUCTS & REFINING CO., 1924 Washington Blvd., Chicago, Ill., has been incorporated with a capital of \$200,000, to manufacture refined oils, gasoline, etc. The incorporators are D. M. Kelly, Henry F. Snyder and Frank Mooney.

THE SAND LIME PRODUCTS CO., Detroit, Mich., has been incorporated with a capital of \$50,000, to manufacture bricks and other sand lime products and byproducts. The incorporators are John Wyman, Harry W. Gould and Theron C. Taylor, 2436 West Grand Blvd.

THE COMMUNITY CUT GLASS CORP., Buffalo, N. Y., has been incorporated with a capital of \$100,000, to manufacture glass products. The incorporators are F. Schneider, J. H. Stoffel and F. J. O'Connor. Harding & Harding, attorneys, Buffalo, represent the company.

THE EMPIRE OIL CORP., Long Beach, Cal., has been incorporated with a capital of \$350,000, to manufacture petroleum products. The incorporators are J. D. Hawk, E. E. Bean and Charles R. Lewis, Long Beach. The company is represented by Louis N. Whealton, 206 Marine Bank Bldg.

THE KENYON BRICK & TILE CO., Oklahoma City, Okla., has been incorporated with a capital of \$125,000, to manufacture brick, tile and other burned clay products. The incorporators are W. A. Kenyon and David Oliver, Oklahoma City.

CARRIS & WATSON, INC., Newark, N. J., has been incorporated with a capital of \$50,000, to manufacture paper products. The incorporators are Milton Carris, Robert Watson and A. E. Jock. The company is represented by Michael Silver, 790 Broad St.

THE ALEXANIAN HOOPOE MFG. CO., South Bend, Ind., has been incorporated with a capital of \$10,000, to manufacture chemical products, cleaning compounds, etc. The incorporators are J. G. and M. G. Alexanian, South Bend.

THE DALFORD OIL REFINING CO., Wilmington, Del., has been incorporated with a capital of \$100,000,000, to manufacture refined oil products. The company is represented by the Corporation Trust Co., du Pont Bldg., Wilmington.

THE SIMPICI-T FOLDING BOX CO., Pawtucket, R. I., has been incorporated with a capital of \$25,000, to manufacture paper boxes and other containers. The incorporators are Daniel L. Baxter, Pawtucket; Howard R. Thayer, Cranston; and Hayward T. Parsons, Providence, R. I.

THE PERMA-COLOR-LITE PRODUCTS CORP., New York, N. Y., has been incorporated with a nominal capital of \$5,000, to manufacture enamels and kindred specialties. The incorporators are W. J. Snell, W. R. Respass and L. J. Smith. The company is represented by L. F. Stumpf, 233 Bway.

THE ANTHRACITE REFRACTORIES CO., Blakely, Pa., has been incorporated with a capital of \$150,000, to manufacture refractory products. D. J. Beardslee, Peckville, Pa., is treasurer.

THE EASY PRODUCTS MFG. CO., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture paints, varnishes, etc. The incorporators are W. J. Cook, J. H. and J. K. Barry. The company is represented by William M. Rysdyk, 76 Montgomery St., Jersey City, N. J.

THE NEW ENGLAND REFINING CO., Providence, R. I., has been incorporated with a capital of \$30,000, to manufacture refined oil products. The incorporators are William H. Butcher, E. C. Rohman and Lawrence J. Golden, 692 Summit Ave., Jersey City, N. J.

Capital Increases, Etc.

THE RADIUM LUMINOUS MATERIAL CORP., 58 Pine St., New York, N. Y., has filed notice of change of name to the United States Radium Corp.

THE CROWN OIL CO., Syracuse, N. Y., manufacturer of refined oils, has filed notice of increase in capital from \$150,000 to \$300,000.

THE CONTINENTAL CHEMICAL CORP., Watseka, Ill., has filed notice of increase in capital to \$25,000.

THE MIDDLETOWN RUBBER CO., Middletown, N. Y., has filed notice of increase in capital from \$1,000,000 to \$2,000,000.

THE AUDUBON CHEMICAL CO., a Delaware corporation, has filed notice of organization to operate in New York, with a capital of \$250,000. H. N. Bennett, 47 West Sixty-third St., New York, represents the company.

THE SCOBELL-MILLER CHEMICAL CO., Rochester, N. Y., has filed notice of change of name to the Scobell Chemical Co.

THE J. A. C. PRODUCTION CO., Danville, Ill., has filed notice of increase in capital from \$50,000 to \$400,000, at the same time changing its name to the Vermillion Oil Co.

THE UNIVERSAL TRANS-LEVER SPRING CO., Detroit, Mich., manufacturer of steel springs, etc., has filed notice of increase in capital from \$75,000 to \$250,000.

THE STANDARD DRUG & CHEMICAL CO., 817 North Ashland Ave., Chicago, Ill., has filed notice of increase in capital from \$10,000 to \$50,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society are holding a joint meeting in New York, Sept. 6 to 10.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN PEAT SOCIETY will hold its fifteenth annual convention at the Hotel Commodore, New York City, Sept. 7, 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del., Oct. 18 to 20.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Number 11

The Facts About American Dyes

THE other day we heard an estimable gentleman fulminating about dyes. He is a large wholesaler of cotton goods and he protested with vigor against this hullabaloo that is being made to keep German dyes out of the country while the very kind that is needed for his goods—to wit, vat dyes of the indanthrene type—are not made here.

We delivered a little reply about the anthracene base of most of them, told how pitch with the anthracene extracted does not seem available for roads and roofing, but that abroad, where pitch is largely used as a binder for coal briquets, the extraction of anthracene made no difference, but we felt that our reply was weak. Indeed it was weak, for we subsequently learned that there is plenty of anthracene available in this country but that manufacturers of dyes generally do not know how to use it. From what we can learn it appears that no American manufacturer has thus far succeeded in making, successfully and economically, a full line of the special type of vat dyes generally known by the German trade names of "indanthrene," "ciba" and "algol" colors. Their special use is for such cotton goods as shirtings. All the other colors with the exception of some of the related alizarines are made here in quantity and of standard quality. Vast amounts of indigo of supreme quality and a number of true alizarines of domestic manufacture are at hand as vat dyes. The only real hitch has been in those of the indanthrene type and we are assured that two American concerns are making a few indanthrene colors that are wholly up to standard and that they are producing them in quantity. The full line, however, has been "coming along" for five years, and experience teaches us to be conservative in waiting for them.

But why worry! *The very vat dyes which are needed are today being imported in large quantities under license!* There is no shortage of any kind of dye needed by American textile manufacturers, either in quantity or in quality. Not only the old dyes but even the new ones are available.

Then what is the trouble? We think it would have been better if the makers of dyes had been as frank in admitting their failures as they have been in telling their achievements, but this habit of frankness has not yet been incorporated into the *mores* of American industry. And it is not the cause of the present discontent. The discontent comes from improperly dyed goods. And why are improperly dyed goods offered for sale? The answer is the same as that given after mature thought by an old elder in the Bible class when the dominie asked him why GOD hardened PHARAOH'S heart. "He had," replied the elder, "various reasons."

Now among our various reasons is the cost of labor.

One dip costs less than several dips, and the high wages paid to dyers induce many textile manufacturers to take the shortest cuts to get results irrespective of quality. This, we believe, is a leading reason. Then, too, there used to be a nasty situation in dye houses in that dyers wanted bribes—and got them in profusion. They don't get them any more, and this may have a bearing. Again there used to be German competition, and the Germans are good dyers. There are just such good standards of quality on the market today, but the public does not know the trademarks. Sulphur black is plentiful and cheap, and no better sulphur blacks were ever made than are made by a number of American concerns. Plenty of dyers can and do apply it. But direct black, which does not hold so well in the wash, may be put on at less cost, and one pound of it will take the place of two or three of sulphur black. And here a new cause of trouble appears—drygoods pass through many hands before they reach the retail counter, and the converter who handles the goods may have little more than a cent a pound margin in the transaction. He therefore orders the material dyed at the lowest cost, and the cheapest goods win out with the buyers. So the fault is not alone with the dyer. A good part of the blame rests with the manufacturer, the converter, the jobber, the wholesaler and the retailer as well.

As for woolens and silks, there has been no shortage of any dye needed for years. Light, delicate shades never were fast to light, they are not now and there is no promise of their becoming so. But 1914 was seven years ago and people forget a great deal in seven years. One of the things they have forgotten is that such garments used to fade.

So we come back to the statement which we reaffirm—that every dye, the use of which has not been given up because of its defects, is available to the American dyer today. In addition to this there are a few new and better dyes to be had which were not procurable before the German war. Still more, American dyers are proficient in their art; not all of them, perhaps, but the proficient ones are here and they know how to get the best results obtainable. Improperly dyed goods are on the market and they are offered because there is more profit in them for somebody than there would be if the best that can be had were offered. If the statement is made that "We cannot guarantee these goods as to color because German dyes are not available," it is false. It is made either in ignorance or in cupidity. It may explain the price or the ignorance of the buyer, but it does not state a fact.

The American public buys on finish rather than on intrinsic quality. Whenever it demands quality and insists on it, it can have it. Duty-free dyes would not give us cheaper or better clothing. Duty-free textiles would, but do we want duty-free textiles?

Fundamental Conceptions

Underlying Metallurgical Advance

TECHNICAL literature and scientific transactions—at least as far as metallurgical science is concerned—seem now to be almost exclusively occupied with quality rather than quantity of output, with inquiry into hidden causes rather than exposition of their effects. One ton of metal of excellent properties, great reliability and endurance is apparently more interesting than 600 tons of ordinary stuff. Investigators are more interested in the one condenser tube which fails than the thousands which prove satisfactory in every way. Research men are borrowing the utmost resources of physics and chemistry to discover the mechanism of so common an occurrence as a breaking axle.

But are these investigations, these accounts of failures, these lists of physical properties, descriptions of laboratory manipulations, and speculations about things too small to be seen in the microscope, are these things of any real value to work-a-day life? Are they more than mere star gazing, not worth the paper they are printed upon?

Undoubtedly they are of value, if for no other reason (and there are many others) than that from them will emerge, some time, somehow, the idea whose development and wide application will be the mainspring of the next epochal movement in metallurgy. It would not be surprising if that idea has already been born!

It seems to be a fact that civilization moves forward in sharp rushes—advancing a certain detail very rapidly from a position which it had maintained for years, even centuries, to another position of advantage and apparent rest, only to be followed by a further striking advance on some other sector. Ancient Egypt furnishes an early example. Savants affirm that the Egyptians found something, no one now knows what it was, but they thought out some great idea, which in not more than a short century led that people forth from the place where they were barely able to range a few stones around their dwellings as rough boundaries or defences, to the pinnacle of skill in cutting, fitting, transporting and building huge blocks of granite into pyramids and sphinxes.

Last century it dawned upon some men in the iron trade that mechanical handling could be applied to metallurgical processes, and in twenty years JOHN FRITZ, HOLLEY, BROWN and WELLMAN (to mention but a few) led that remarkable "Duquesne Revolution" which increased the capacity of blast furnaces and steel mills one hundred-fold. We could build them bigger, but what's the use? They would lose flexibility, or rather adaptability, and be more than ever subject to intermittent operation, with consequent interest and overhead charges mounting to ruinous proportions.

So, it may be repeated, metallurgists have been for some years groping, somewhat haltingly, for the new idea which will carry them forward on the next advance. But has not the new conception already been dimly seen?—the realization that physical properties and reactions must be interpreted in terms of forces acting between atoms, even within the very structure of an atom.

How else can the field of alloying, stupendously great, almost uncharted, without apparent form, a tangle, be mapped out and comprehended? What else is common to such widely divergent things as hardest tool steel and softest lead, toughest copper and most brittle tungsten,

infusible calcium and liquid mercury, the corrosion of metal and the smelting of ore? Fundamental hypotheses and theories four-square with our ever widening knowledge of the atom itself are the only ones which will allow the tremendous mass of experimental information to be classified and truly understood, but, more important still, will enable one to predict with fair accuracy the expected result of a hopeful investigation—to steer a course which will lead to those new discoveries and valuable improvements which will form the milestones of civilization's advance.

Suggesting a New

Branch of Chemistry

WE HAVE so many kinds of chemistry—inorganic, organic, physical, colloid, photo and such a lot more—that it will scarcely do harm if we add still another division, and for this we propose the term Credulochemistry. It is published almost exclusively in daily newspapers, and is, in effect, chemistry that isn't so. A few years ago it flourished more actively than it does now, but we still have remarkable manifestations offered for study. A curious feature is that contributors to this amazing field of research are almost invariably wholly ignorant of science. They do not have to reason or think; they just make "expurments."

The latest step in credulochemistry we gather from the New York *Herald*, but it was also published as a news item in several other leading journals. This "special despatch" was dated Laporte, Ind., and it set forth the news that WALTER BUNTON, twenty-eight years old, a war veteran with a wound stripe, employed by the New York Blower Co., had discovered the "lost art" of hardening copper. This is a favorite stunt, and has been discovered so many times that it seems a pity that, after all the inventions, copper isn't really any harder than it is.

Mr. BUNTON of the Blower company seems, according to the report, to have had better luck. First he found an ash-can in which were some leaves of an encyclopædia which told of "an ancient metallurgist, incidentally a murderer, with whose death the secret of hardening copper was lost." Then he proceeded to experiment, and, presto! there was his metal which, according to the *Herald*, "is said to be the hardest metal known, except for one called 'Steelite,' (*sic*). It means cutting tools for lathes that will not strike sparks . . . electric motors and generators that will not burn out"—it means, in other words, an awful lot. Then he went to Gary, Ind., and saw Judge GARY, showing him his discovery, and he, as soon as BUNTON finished talking, said: "Name your terms."

(Now isn't that just like Judge GARY?)

BUNTON replied: "One million dollars . . . and two cents a pound royalty."

"We will let you know. Good day," answered the chairman of the board of the U. S. Steel Corporation, and on Friday, the paper says, "a letter came accepting the terms." The account closes with, "BUNTON is to be married in October." That gives it what they call on the stage "the heart interest."

Now the people at the Steel Corporation do not know anything about this great find and strategic purchase, and neither does anybody else as far as we can find out. It is merely an eruption of credulochemistry. A study of its origins would be interesting. But we wish they would stop hardening copper.

Russian Chemists And Organic Chemistry

IN A monograph on "The Chemistry of the Non-Benzene Hydrocarbons," by Dr. BENJAMIN T. BROOKS, which will soon be published, over half the citations refer to work by Russian chemists. We need to be reminded of the splendid work, the masterful research in chemistry, more particularly in the organic field, which was in progress in Russia when the German war began. Where are those men now? What are they doing? Have the Soviets put them to work sweeping streets because it required capital to prosecute chemistry and therefore the science itself is a phase of wicked capitalism? Where are IPATIER, KISHNER, MARKOWNIKOV, KANOWALOV, ELINSKY, BREDT, OSTROMUISTESENSKI, LEBEDEV and CHARITSEKOV? Where is P. WALDEN, who was here in 1912? The rubber industry is in a bad way, and research is the best cure for bad times. Wouldn't it be a good plan to send out a search party to find OSTROMUISTESENSKI? His contributions to the chemistry of rubber have been of high rank, and his splendid talent and understanding would be a godsend to the industry. If these men are not at work at their chosen calling it would be an investment of supreme value to find them and to provide opportunity for them. It is no reflection on American chemists to say that these Russians are needed. Talent is always needed in science, and men with a real vision of chemistry have to be born as well as made. We cannot induce the quality by fluttering a flag over their mothers' childbeds. The Germans thought they could and that chemistry was Kaiserlich-Königlich-Deutsch, but they found out their mistake. As soon as we begin to think that American chemists are the only pebbles on the beach, it will be sunset time with us.

Relations In Wage Rates

THE decision rendered last week by Judge LANDIS in the Chicago building trades dispute is interesting from several viewpoints. When first solicited to act in the matter Judge LANDIS refused to undertake to set wage rates as long as certain working conditions were allowed to continue. Various changes were then made in the rules, in the direction of efficiency, and Judge LANDIS consented to act in the matter of rates. It is well that the conditions making for waste in building operations in Chicago were thus emphasized and that some correction has been applied. There cannot be too much publicity given to the extravagant waste of time and wages that has characterized building operations in many centers.

In CHEMICAL & METALLURGICAL ENGINEERING of July 27, 1921, reference was made to statistics gathered by Dr. RALPH G. HURLIN, statistician of the Russell Sage Foundation, covering commodity prices and wage rates for a century or so. It was shown that from 1820 to 1910, while wages in general almost trebled, the wages of five selected classes of artisans ran quite uniformly at 80 per cent above the rate for common labor. In the past few months we have seen common labor receiving 25 to 30 cents an hour in many descriptions of work in various parts of the country, while artisans were demanding a dollar or more an hour. This brought up the question whether conditions had changed from those that ruled for perhaps a century or longer, so that skilled labor should now be worth more than for-

merly in terms of dollars in relation to common labor. Considerations that are obvious would suggest a contrary conclusion.

In this connection the award of Judge LANDIS is of particular interest. Eight of the skilled crafts involved will receive less than 85 cents an hour, while a few will receive a trifle more than a dollar. "Common labor" is evidently defined peculiarly in the Chicago building trades, for the reports show that Judge LANDIS has set at least four rates for different classes of common labor, 47½ cents, 50 cents, 70 cents and 72½ cents. A common labor rate of 50 cents and an average of 90 cents for skilled labor would show the 80 per cent relation of skilled over common labor that Dr. HURLIN's statistics indicate is worthy of much respect. A curious point is that the previous standards in Chicago were \$1 for common labor and \$1.25 for skilled labor, showing a 25 per cent premium for skill instead of 80 per cent. One experiences no difficulty in concluding that the wages were due to membership in unions and the restrictions that had been thrown about building operations. One could work this out by some very simple algebra, but it is not necessary to set down the equations. Take 31 cents for common labor and 56 cents for skilled labor, which makes the latter approximately 80 per cent above the former. Then add to each rate 69 cents an hour as the part played by the unions and one has \$1 for common labor and \$1.25 for skilled labor.

Salvage for The Wise Ones

There is a certain frame of mind to which a cemetery is, if not an antidote, at least an alleviation. If you are in a fit of the blues, go nowhere else.—Stevenson.

PATIENT men will amusedly tolerate the talk of the fellow in these days who propounds a philosophy of optimism unsupported by facts. The most imperturbable man, however, loses all control in the presence of the individual carrying the morbid mien in bad industrial weather and mounting fleecy clouds to air castles during periods of booming business.

Last year this latter chap vowed the sunny season would never end because it was upon us. It has taken a period of hard depression to convince him to the contrary until now he is just as certain that business will be bad for the next decade. The pitiful thing about the whole situation is that his type is in the majority and is found even in our so-called big business circles. Were the advice of STEVENSON taken seriously, the burying grounds of this country would have no standing room available.

Keen thinkers are not talking so much about the good times coming, but realizing that the worst has happened in many industries, are quietly preparing to reap a profit from the weak-hearted ones. Opportunely purchasing failing business enterprises, stocking up on materials and equipment at bargain prices and slowly building up organizations for the future harvest are all a part of their plans. Accumulating economic goods on a lowered tide, they will witness the same old spectacle of their ships coming in with the full flood of industrial prosperity and the graveyard artist, now become a horn-tooter, standing by anxious to purchase the cargoes at the highest figures.

The repetition of the sun-moon ocean tide is no more certain than the return of prosperity in the greatest creditor nation.

MEMBERS AND VISITORS, CANADIAN MEETING, SOCIETY OF CHEMICAL INDUSTRY

1—Dr. J. P. Longstaff, secretary of the society. 2—Dr. R. F. Ruttan, president of the society. 3—Sir William Pope, K.B.E., F.R.S., retiring president. 4—E. F. Smith, president of the American Chemical Society. 5—William H. Nichols, past president of

the American Chemical Society. 6—T. H. Wardleworth, vice-president of the Society of Chemical Industry. 7—C. S. Garland, A.R.C.Sc., chairman of Lighting Trades, Ltd., and vice-president of the Society of Chemical Industry.

Canadian Meeting, Society of Chemical Industry

Large Number of Delegates From Great Britain and Visitors From the United States Gather in Montreal and Later Experience the Hospitality of Various Sections of Canada—Dr. R. F. Ruttan Elected President—Summary of Papers Presented

THE extended tour of the delegates to the annual meeting of the Society of Chemical Industry was concluded on Sept. 7, and we give below a short summary of the principal events, of the papers and discussions and of other features in the itinerary. Photographs and particulars of the principal delegates have already appeared in these columns. Some were prevented at the last moment from attending, these including the Hon. Treasurer of the society, E. V. Evans, and Dr. MacWilliam, the well-known metallurgist of Sheffield. Additional members of the party are Peter Kerr, chemist to the Shell Mex interests, W. Gordon Adam, of the Gas Light & Coke Co., and Keith Benham, managing director of the Universal Grinding Wheel Co. of Stafford.

The passage on the "Melita" was uneventful and good weather enabled the ship to establish a record crossing of some hours under seven days to Quebec.

The delegates' reception at Quebec was of the most cordial and hospitable description, and it is really extraordinary how much the party was able to see of Canada in a very short space of time, thanks to the admirable arrangements which were made. Visits to Ste. Anne de Beaupré, the Golf Club, Kent House, Montmorency Falls and the battlefields constituted, with Sir George Garneau's dinner at the Garrison Club, the first day's program, while on Saturday the Lieutenant-Governor's luncheon at Spencerwood was a really notable occasion in the happiest of surroundings. In the afternoon the party left for the Manoir Richelieu, Point-a-Pic, Murray Bay, and the beautiful surroundings and invigorating atmosphere of this delightful resort did much to cement the intimate and cordial relationship which had already sprung up between the delegates and their Canadian hosts.

Incidentally, progress was made in arranging the following week's program and certain departures from a somewhat hidebound precedent were necessary in conducting a meeting of this kind in another continent.

The Annual Meeting

The annual meeting was held at McGill University on Aug. 29, and it was announced that more than 225 members of the society had registered at the Chemistry Building. In addition to the British visitors several notable American chemists were also present, including Dr. Edgar F. Smith, president of the American Chemical Society; Dr. C. H. Herty, and Dr. W. H. Nichols, president of the Allied Dye & Chemical Corporation. Theodore Wardleworth, the chairman, called on the Rt. Hon. Sir Charles Fitzpatrick, K.C.M.C., Lieutenant-Governor of the Province of Quebec, who extended a hearty welcome and a personal message of good will from the Prime Minister of the Dominion. Sir Charles eulogized the work that the members of the society had done during the war and expressed the hope that the same high ideals would animate them in their reconstruction tasks.

At the request of the Canadian Section, and of its three branches, the Section has been dissolved and separate sections have been established at Montreal, Ottawa and Toronto. A new section has also been formed at Shawinigan Falls, so that the society has now five Canadian sections—namely, at Vancouver and at the four centers above mentioned. There has been formed an executive committee for Canada, consisting of the chairmen and secretaries of the five sections, to arrange for the annual convention of chemists and to take charge of matters affecting the Canadian chemical industry.

A conference on the standardization of chemical plant was held at the Institution of Civil Engineers in July, 1920. It was attended by representatives of government departments and of scientific bodies interested, including the Society of Chemical Industry. It was unanimously recommended that a Chemical Engineering Committee of the British Engineering Standards Association should be set up, and this was subsequently approved. The representatives of the society on this committee are Prof. Hinchley, Capt. Goodwin, Mr. Reavell, Mr. Garland and Dr. Ormandy.

1—Group of some of the party on S. S. Melita.
2—Chief Justice William H. Taft at Murray Bay.
3—Dr. R. F. Ruttan, Chief Justice Taft, Sir William Pope.

4—Dr. R. F. Ruttan, president Society of Chemical Industry
5—Sir William Pope, retiring president of the society.
6—Dr. J. P. Longstaff, secretary of the society.

President's Address

Sir William Pope, the retiring president, brought out forcibly the good effects resulting from the co-operation of all the peoples of the British Empire and dwelt especially on the part played by the great Dominion of Canada. He then outlined the wide field covered by the society, and after mentioning that the society's financial status is now quite satisfactory and that great strides are made by the Council and publication committee to broaden the scope of the *Journal of the Society of Chemical Industry*, he spoke with enthusiasm about the great problems now confronting the British chemical industry. He said in part:

"Seven years ago the situation and the outlook in all branches of scientific industry were very different from those which now confront us. In 1914, certain of the chemical industries of Great Britain were expanding slowly but steadily, while others were slowly but just as surely shrinking before foreign competition; in some of the chemical industries Great Britain was supreme, but in others we were losing ground. The interval has seen the commencement and the conclusion of a great conflict, a war which has reduced to mediocrity several of the dominant European powers, and has left nearly every nation struggling under an accumulation of debt.

"The problem now is an entirely novel one in that it is accompanied by certain factors which were previously absent or which were at any rate of subsidiary importance. Thus it cannot be doubted that the bonds uniting all parts of the British Empire have become far stronger in consequence of the events of recent years; further we realize to a greater extent than ever before that for purposes of production our empire must be, if not absolutely self-contained, at least in possession of modes which could be rapidly mobilized so as to render us self-contained.

"In the past we have, I venture to think, endeavored to build up our chemical industries far too much on the lines which proved so fruitful in Germany. I am

speaking now not of the heavy chemical industry, in which we have always been to the fore, but of those industries which involve the production of the use of a great variety of more or less complex organic compounds. The organic chemist has long had before him, as one great object of his work, the artificial production of the myriads of organic compounds which we find among animal and vegetable products; he may be justly proud of his achievements in this direction and the success attained justifies our belief that we shall within quite a short time be able to prepare in the laboratory any compound substance formed by the animal or plant. Immediately some important natural product of commercial value is produced in the laboratory, the German technologist has sought to convert the laboratory method into a works process capable of competing with that of the plant or animal.

"My point in suggesting that we have erred in adopting German views concerning the methods and aims of chemical technology, without reflecting that economic conditions in Central Europe are entirely different from those which prevail in the British Empire regarded as a whole, perhaps calls for some explanation. The object of all technology consists in converting raw materials of inorganic origin into products of greater value by expending upon them a certain amount of labor, and a certain amount of energy. To a Central European nation labor means high wages to its population and energy means mainly coal or waterpower; only one type of technological process is thus in the main to be considered, and this is one in which certain raw materials enter the works to be handled by costly labor and to be treated by the burning of fuel, which is another form of costly labor.

"We have other methods for obtaining similar results, methods which are available in many cases but have been worked out in only a few cases."

He cited the specific example of the synthetic india rubber made in Germany as compared with the natural

product from the plantations in the British territory and added:

"It would not be fair to depreciate the installation of synthetic methods for manufacturing complex natural products. Nature in general furnishes us with but one very complex member of any particular class of organic compounds. Thus the numerous plants which produce indigo yield but minute proportions of other compounds of a similar type and, in this instance, the chemical technologist has succeeded in manufacturing a whole range of valuable dyestuffs of the indigo family which do not occur among vegetable products; his efforts have to this extent been amply justified, but it is difficult to believe that synthetic indigo itself would ever have been able to compete in the market if a similar amount of scientific skill and intelligence had been devoted to the improvement of the cultivation and utilization of the indigo plant. The work which is now being done by Armstrong, Davis and others on natural indigo may well result in the re-establishment of the Indian indigo plantations.

APPLICATION OF LOW POTENTIAL ENERGY

"The last century has witnessed two great phases in the development of practical chemical work. Roughly speaking, it may be said that the progress of chemistry up to about forty years ago, great though that progress was, resulted from the application of rather fierce methods; a time came, however, when it was recognized that much was to be learnt, especially in organic chemistry, by the study of delicately balanced reactions in which the practical methods applied were devoid of violence and in which conditions, such as concentrations, temperatures and the like, were carefully controlled. The organic chemistry of to-day does not distill fragile organic compounds through red-hot tubes; it proceeds by more subtle methods which, nevertheless, have greatly developed the broad knowledge of the science bequeathed to us by our predecessors. In its adoption of milder modes of operating and its consequent application of energy at a low potential, organic chemistry is approximating in its laboratory methods to those which occur in plants and animals; but the chemical changes which occur during the course of animal or vegetable life are still far more complex than those brought about in the laboratory. This complexity doubtless arises from the utilization of low potential energy in the living organism; temperature changes of more than 1 deg. C. are not permissible in the healthy animal organism. The great majority of the chemical reactions which take place in living matter occur catalytically in colloidal media.

"While the first great epoch in the history of organic chemistry was marked by the application of violent experimental methods, the second developed milder modes of procedure; the third epoch, which is in course of inauguration, will bring us into direct competition with the experimental chemical methods practiced by living matter. It is impossible to doubt that a vast expansion of organic chemistry will be witnessed by many of us, an expansion which will result from an imitation of the gently effected chemical operations carried out in the animal and vegetable creation.

"While this prophecy is not a mere surmise as to the nature of the next step forward to be taken by the science of organic chemistry, but is rather of the nature of a logical deduction from past events, it is perhaps surprising that more use has not been made

of the chemical methods of living matter for technological purposes."

He then directed attention to the fact that up to the present far too little progress has been made in the direction of combating the different types of parasitic vegetable and animal life, and finally spoke on the pressing need of a better use of the petroleum resources.

In moving a vote of thanks to the president, Dr. R. F. Ruttan, in a happy speech, referred to the progress made in the application of biochemistry to industry in recent times, instancing the Weizmann and Fernbach processes of starch fermentation for the production of acetone and the successful way in which these and the synthetic production from acetylene had been carried through at Shawinigan Falls.

OFFICERS ELECTED, LUNCHEONS AND BANQUET

The remainder of the business was of a purely formal character and a luncheon followed at the Ritz-Carlton Hotel under the chairmanship of Dr. Milton Hersey, at which a civic welcome was extended by Dr. Dubeau on behalf of the Mayor of Montreal.

On the following day H. W. Matheson of the Shawinigan Company presided over a luncheon at the Windsor Hotel at which Sir F. Williams-Taylor was the guest of honor. Sir William Pope took the opportunity of addressing the members of Rotary Club of Montreal at the same time and gave them a digest of his writings on the future of gas warfare and its relative merits and efficiency as against other forms of destruction. The banquet took place at the Engineers' Club.

The officers elected are: President, Dr. R. F. Ruttan; vice-presidents, Dr. J. L. Barker, C. S. Garland and Sir William Pope; members of the Council, H. Allan, F. Armstrong, J. W. Hinchley and J. D. Wilcock.

Technical Sessions

At the technical sessions papers were presented by speakers prominent in their various lines.

NEED FOR REFORM IN THE EDUCATION OF CHEMISTS

Prof. Lash Miller, speaking on the need for reform in the education of chemists, pointed out that far more students were taking up chemistry than were dreamed of a few years ago. The training given them is the same today as it was when chemistry was a purely experimental science. There is need for reform of chemical language, to make terms and formulas mean something to the students learning them.

THE LAURENTIDE HIGH-SPEED NEWS MACHINE

A paper on the Laurentide high-speed news machine, by George D. Kilberry, was read by J. L. Stephenson.

The new 166-in. news machines installed in the Laurentine Company's mill at Grand Mere, Que., probably represent the very best effort heretofore applied to the design and construction of news machines, and the recent results obtained amply justify the Laurentide Company in believing that it has reached the goal selected—namely, marketable paper at 1,000 ft. per minute or better as a continuous operation.

These machines embody no new principle in paper making, but have some features of design not common to most machines, chiefly the method of putting on new wires, the application of suction couch and suction press rolls, the novel arrangement of compressed air jets for passing the tail or ribbon of paper from couch to press and between the presses as well as at the

calenders and reel and a very generous use of ball bearings at the wet end of the machine.

The fourdrinier part of the machines is constructed without the usual shaking arrangement, as it has been demonstrated that there is no more need for shake on a news machine than five wheels on an automobile.

THE ACTION OF THIOCYANATES ON CELLULOSE

R. H. Clayton read a very important paper on "The Action of Thiocyanates on Cellulose" by R. H. Clayton and H. E. Williams. The contention of their paper is that solvents for cellulose must have the following specific properties:

1. High solubility in water.
2. High boiling point in concentrated solution.
3. Suitable viscosity and of a positive, but not too great, heat of dilution.
4. Mixed salts not to react chemically.

Diagrams showing the correct conditions were shown and explained.

Of all the cellulose solvents examined, calcium thiocyanate is the most suitable; it has the further advantage of being derived from a cheap base, and hence has been most considered from the industrial standpoint.

Following the discussion on this paper a moving picture of the manufacture of paper showing the complete operation from the tree in the forest to the roll of finished paper leaving the mill was presented by A. L. Dawe, secretary of the Pulp and Paper Association. This film depicted the operation at Price Bros.' plant, Kenogami, Que., and is considered one of the finest industrial films that has ever been taken.

PROPERTIES OF PURE HYDROGEN PEROXIDE

Dr. O. Maass' address dealt with the preparation and properties of 100 per cent peroxide, a research carried out at McGill University.

Hydrogen peroxide is the name commonly applied to an article which may be procured in any drug store, but this really consists of a 3 per cent aqueous solution which generally contains as well inorganic salts, a little acid and other impurities. The water and other impurities are removed in three stages. The first consists of a vacuum concentration and distillation to a 35 per cent pure aqueous solution, this is then concentrated to a 90 per cent solution and the latter subjected to fractional crystallization on the end product of which is the 100 per cent. Special apparatus was designed for this work, including a sulphuric acid pump, which alone made it possible to obtain large yields. Strong solutions of hydrogen peroxide were prepared in the past and were reputed as being highly explosive and several serious accidents are recorded. This instability is due to the presence of impurities. Pure acid-free hydrogen peroxide is not explosive.

OBSERVATIONS ON THE CHEMISTRY OF RUBBER

In "Some Observations on the Chemistry of Rubber" Prof. G. S. Whitby touched on a variety of points of interest in the researches which he and his co-workers have recently conducted at McGill University into the chemistry of raw rubber and the vulcanization of rubber. He described an investigation of the resin of rubber, which represents the first successful attempt to elucidate in some degree the problem of the chemical nature of a constituent of raw rubber which, although present in only a small proportion, has an important influence on the behavior of the rubber when the latter

is vulcanized and in other ways. Dr. Whitby's investigations show that a considerable number of crystalline substances can be isolated in small amounts from raw rubber. One of these substances is an interesting sugar-like body, which was known to occur in rubber latex but the presence of which in prepared rubber was unexpected, on account of its great solubility in water.

Experiments were described on the artificial conversion of rubber into a resin as a result of the absorption of oxygen from the air under the influence of catalysts. One mode of carrying out this conversion which Dr. Whitby has worked out may lead to the production of lacs or varnishes from rubber. The study of this conversion is also of importance because of its relation to the "perishing" of rubber goods.

MANUFACTURE, PROPERTIES AND EMPLOYMENT OF HEAT-INTERCEPTING GLASSES

Prof. Celert Alleman in introducing the subject of heat-intercepting glasses described how silver nitrate when exposed to the action of light passing through ordinary glass is discolored, while if placed in a container of special glass no change is noticed. Similarly smoked bulb thermometers exposed under the same conditions will record different temperatures, that in which the ordinary glass is used showing a higher temperature than that protected by the special glass.

Sir William Crookes was the first to investigate glass with the object of securing a spectacle glass which would protect the eyes from heat and ultra-violet rays and reduce glare. He concluded that cerium salts were most effective in this way and black mica added to the melt produced a glass which almost completely obstructed the invisible heat rays.

About five years ago Mr. Sherman, then chief chemist of the Pennsylvania Wire Glass Co., conducted 227 experiments using various mixtures and confirmed Crookes' work and produced a more brilliant glass by a slight manipulation of the furnace temperature. This material is now a commercial product known as actinic or heat-intercepting glass, manufactured into plate polish, plate wire, plate proof wire, aqueduct wire, ribbed wire and corrugated wire glass.

These different types were described, emphasis being laid upon the importance of annealing. An instance was given of the resistance of the corrugated wire glass to shock. A 2½-in. steel smokestack 24 in. in diameter and 25 ft. in length fell in a severe windstorm on the corrugated wire glass roof of a large boiler house. While two plates were destroyed and the remainder of the glass cracked or bent, it was not shattered and did not leak, although the steel beams on which the glass rested were bent out of line about 3 in.

Tables were shown covering tests made on houses erected of the various types of heat-intercepting glass showing the marked difference between the temperatures inside and outside the house and also showing the high percentage of light transmitted, the lowest being 72 per cent.

PREPARATION OF SYNTHETIC ORGANIC CHEMICALS

In dealing with "The Preparation of Synthetic Organic Chemicals at Rochester," Dr. C. E. K. Mees first took up the status of chemistry of the present day as compared to that of ten years ago, emphasizing the need of research and its co-operation with industry.

Before 1914 the supply of synthetic organic chemicals was entirely in the hands of one or two firms in Ger-

many. With the outbreak of hostilities, this supply was cut off and the effect was soon felt. Many researches had to be abandoned. Prof. C. G. Derick of University of Illinois met the situation by inviting the most promising students to work during vacation on those organic compounds most needed. This was a unique step, the reactions being conducted on a scale unusual in research work. As it was very evident that the supply of organic chemicals was inadequate, the Eastman Kodak Co. in 1918 decided to enter the field, having no prospect of immediate profit. The work undertaken was: 1. Synthesis of compounds which are not prepared technically but are required for laboratory purposes. 2. Purification of technical materials got from chemical manufacturers. 3. Distribution of such technical chemicals in form in which purchased.

Raw materials were obtained largely from dye, dye intermediate, perfumery, explosives and pharmaceutical chemical manufacturers, also from individuals in university and other laboratories. The chemicals produced are classified under: 1. The Eastman chemicals (highest possible purity). 2. The practical chemicals (purity sufficient for synthesis). 3. Technical products (as from large scale manufacturers).

BRIQUETTING OF LIGNITES

Leslie R. Thomson described the work that has been done on lignite briquetting by the Lignite Utilization Board of Canada since its inception in October, 1918, and illustrated his paper with a number of diagrams, drawings and tables of results.

The Provinces of Manitoba and Saskatchewan are largely dependent upon American anthracite coal for domestic heating purposes and during the years preceding the war about 500,000 tons was annually imported. The price of this imported coal naturally increased as one went westward owing to the higher freight charges. It continued to find a market until the price went so high that the consumers were willing to put up with the disadvantages of the much cheaper Alberta coals. This "peak" line runs in a general north and south direction through the eastern part of Saskatchewan. Directly beneath this area, however, there are very large deposits of rather low-grade lignites, which, after carbonizing and briquetting, are capable of being converted into a fuel of high calorific value.

The Lignite Utilization Board was therefore established by the Canadian Honorary Advisory Council for Scientific Research to attack this problem and if possible to demonstrate the feasibility of producing a satisfactory domestic fuel from these lignites by the method of carbonizing and briquetting. After preliminary experiments at the Fuel Testing Laboratory of the Department of Mines, Ottawa, into various phases of the methods to be adopted, a plant was designed and erected at Bienfait, Sask., to have a capacity of 100 tons of briquets per day and has just been put into operation.

At this plant the lignite is first carbonized by heating to a low temperature in order to drive off the more volatile portion and the residue is mixed with a coal-tar pitch binder under suitable control, and after grinding together the mixture is pressed into briquets in a roll press. The briquets weigh about 2 oz. each and are egg shaped. The summarized results are:

1. It has been possible to make a first-quality commercial fuel briquet from carbonized lignite using any one of such binders as coal-tar pitch, petroleum pitch,

hardwood tar pitch, sulphite liquor pitch, or by using combinations of them.

2. The quantity of binder required is much in excess of that necessary to make a correspondingly good briquet from anthracite fines.

3. A waterproof briquet of carbonized lignite cannot be made using sulphite pitch as a single binder unless the briquets are heat-treated subsequently.

4. The choice of binder does not rest so much with the technical difficulties involved in its use, but with the economic supply of that particular binder. In other words, the Lignite Board has succeeded in making good briquets from many binders.

THE RECOVERY OF PEAT BY AIR-DRYING

Dr. Ernest V. Moore in his paper on "The Recovery of Peat by Air-Drying" described a practical method of turning raw peat into a product of economic value. Peat is a combustible substance produced by slow decomposition of vegetable matter and occurs saturated with water in peat bogs typical of the Northern Hemisphere. To transform raw peat into combustible material it is necessary to reduce its water content of 90 or 95 per cent to about 30 per cent. Drying is effected best by evaporation in the open air.

Great difficulties of collecting peat are overcome by gathering it with a combined excavator and macerator which is supported on caterpillar-tread carrying elements—a device more useful than rails on a soft peat bog. The raw peat is carried by a belt conveyor from the macerator to adjoining higher land, where it is spread from 3 to 6 in. thick on the ground, cut into blocks and allowed to dry in the sun. The blocks are turned to insure uniform drying, and in from 30 to 40 days the moisture content drops to 30 per cent and the peat is ready for domestic use or even for some industrial uses—especially drying operations where a very clean fuel is necessary. Though air-dried peat has twice the volume of an equal weight of coal, Dr. Moore declared that the average householder would gain by replacing 20 per cent of his anthracite pound for pound with air-dried peat.

THE ACTIVATION OF CARBON

Prof. E. G. R. Ardagh in presenting his paper on "Activated Carbon" pointed out that of all the so-called common elements carbon appears to possess greater possibilities both to the investigator in pure science and the researcher in the industrial field.

The paper dealt with amorphous carbon, more especially with its power of absorbing colors from liquids and gases, a phenomenon generally known as adsorption. The progress that has been made in this field is shown to be very considerable particularly during the last ten years. Carbons are today being manufactured that are replacing to some extent fullers earth as a decolorizing and dechlorizing substance in certain industries, and it is not too much to hope that in the not distant future a carbon sufficiently active as a color remover may be produced at a price to supplant bone black in the manufacture of sugar and syrups.

The work of Dr. N. K. Chaney of the U. S. Chemical Warfare Service has thrown an entirely new light on the causes of activity in carbon. Basing its work on Chaney's hypothesis the Chemical Warfare Service of the U. S. was able to produce absorbents for gas mask canisters that were greatly superior to any the enemy were able to make.

Other Entertainment

One of the most interesting functions was that held on the third day of the meeting in Montreal, when an inspiring address was delivered after luncheon by Jacques Bureau, M.P. for Three Rivers, in which district the Shawinigan industries are situated. In pleading for the elimination of waste Mr. Bureau paid tribute to the work of scientists in connection with the pulp and paper industries, which in the St. Maurice Valley alone represented an investment of about \$150,000,000.

"ANCIENT ORDER OF TRISMEGISTIANS" ORGANIZED

On the evening of Aug. 31 the overseas delegates entertained their hosts to a dinner of the "Ancient Order of Trismegistians," which had been formed for the occasion and the rites in connection with which were of a novel and amusing description. The ritual included the presentation to Dr. R. F. Ruttan of a "piece of plate" and of an "illuminated address." The former consisted of a fragment of a dinner plate in a handsome case and the latter was a card mounted in a silver frame illuminated for the occasion by an electric torch and bearing the inscription "Dr. R. F. Ruttan, Society of Comical Industry, Sensible House, Fairand Square, London." As is customary in the Ancient Order, Dr. Ruttan had to give a song when returning the thanks, and these and other entertaining items contributed to a happy and thoroughly enjoyable evening, punctuated by Sir William Pope's usual dry humor.

Visits to Other Sections and Works

Prior to the annual meeting proper the overseas delegates spent some days in Montreal visiting works, such as the St. Lawrence Sugar Refinery, the Gillette Razor Co., the Laval University of Montreal, and similar institutions. They were also the guests of the Harbor Commissioners, who took them for a trip around the harbor in a steam yacht. Frederick W. Cowie, the chief engineer, and Mr. Ross were the hosts at the luncheon given on board, which proved so enjoyable that when it was over the visitors found that they had returned to the spot from which the boat had started, so that the latter was really the one that did the sight-seeing. Several of the visitors were subsequently solaced by a personally conducted tour on land over the grain elevators, warehouses, cold storage buildings and other developments now in process of construction at Montreal Harbor.

On leaving Montreal a whole day was spent at the Laurentide Company's Paper Mills at Grand Mère and in going over the extensive electrochemical industries at Shawinigan Falls, where a section of the Society of Chemical Industry has just been established. Following this, entertainments on a lavish scale were successively provided by the Ottawa and Toronto sections, the visitors being continuously cared for during this period on special sleeping cars. A rough crossing over Lake Ontario preceded their arrival at Niagara Falls, where on Sept. 5 they were officially received by an American delegation including General Kincaid, representing the Governor of New York State; Dr. W. H. Nichols, A. H. Hooker, and the presidents of the American Chemical Society, the American Institute of Chemical Engineers and the American Electrochemical Society. Dinner was served at the Buffalo University Club and in the happiest of surroundings the visitors greatly appreciated their first introduction to American banquet procedure.

The visit to Syracuse, where the plant of the Solvay Process Co. was visited, proved of great interest and the visitors were informed that an inspection by members of learned societies and by industrial chemists was without precedent at these works. In view of the subsequent announcement made by Dr. Nichols that the problem of manufacturing synthetic ammonia had now been completely solved at these works, it is unfortunate that it was not possible to inspect the nitrogen products section. But instead a few of the visitors were able to spend some time in the works of the Franklin Motor Car Co. and to take with them some idea of modern American methods in this important industry.

The general impression among the visitors is that the convention will do an immense amount of good to the status and influence of the Society of Chemical Industry. It has not only been a liberal education to its officials, but all members of the party have learned that it is only by a personal visit to the American Continent that the essential differences in outlook between English and American chemists can be harmonized, such divergences being in the relative size of organization. Thus it is doubtful whether any member of the party had previously realized that Canada's fundamental difficulty and source of her partial dependence upon the United States is the location of her coal fields at the eastern and western extremities, while the intervening districts must largely be supplied with fuel from Pennsylvania, etc., until such time as peat or other fuel developments can partly relieve the situation.

DR. RUTTAN WISE SELECTION AS PRESIDENT

On the personal side there is no doubt that Dr. Ruttan was an eminently wise and suitable selection for the office of president as well as an intensely popular one. He can be relied upon not only to represent the academic but also the industrial and chemical engineering interests of the many different countries over which the society wields its influence. Mention should also be made of the new vice-president, C. S. Garland, managing director of Lighting Trades, Ltd., a constituent of Nobel Industries. Like so many really busy men, Mr. Garland finds time for the development, organization and welfare not only of the chemical industry but of the younger generation of chemists, while for the society his business capacity has been a great asset. Mr. Clayton, Mr. Heap and Dr. Attack represent the manufacturing interests, from which a far larger number of representatives should undoubtedly have attended. Mr. Alliot represents the chemical plant interest and Dr. Jordan is chemical engineer to the British Xylonite Co. Consulting chemical engineers are represented by Capt. C. J. Goodwin of London, whose work in this country and abroad is well known and who is also the official delegate of the Chemical Engineering Group and of the Chemical Industry Club.

NEW SPIRIT OF CO-OPERATION AND PROGRESS

In the past the Society of Chemical Industry has often been held to be an ultraconservative institution, yielding slowly to public opinion, progress and publicity. There are many indications that a new spirit is abroad, and although the number of visitors is small, every one of them will return as a missionary preaching not only the broad principles of progress suitably modified to suit local conditions, but also that spirit of co-operation and personal friendship which the present memorable trip has done so much to foster.

Further Observations on p_H in Natural Waters

Factors Affecting the Hydrogen-Ion Concentration of Natural Waters—Influence of Hydrogen-Ion Concentration on the Removal of Bacteria and Suspended Matter by Filtration, and on the Processes of Disinfection With Chlorine or Its Derivatives

BY ABEL WOLMAN* AND FRANK HANNAN†

IN AN earlier publication¹ by the present authors the theoretical aspects of the influence of p_H on the precipitation of aluminum salts in water were discussed at some length. Since that time it has been possible to accumulate a considerable number of p_H readings on a natural water, the consideration of which should be of interest. The field of knowledge of H-ion concentration is being so diligently explored in all directions, particularly in this country, that it would be a gigantic if not an impossible task to enumerate pertinent references in current literature. It would therefore certainly be invidious to make any selection. However, to any who follow even in a general manner the trend of progress in this field such names as Loeb, Clark and Lubs, Michaelis and Bechhold will offer ample opportunity for intensive study.

In the present discussion it is the intention of the authors to sketch briefly the preliminary conclusions resulting from p_H observations during the past eleven months in a natural water. At the same time the opportunity will be taken to suggest the particular and general significance of such p_H readings as now appear probable.

FACTORS CONTROLLING p_H IN WATER

At this point it may be proper to recall the primary factors which govern the H-ion concentration of waters. These have been set forth in considerable detail and with admirable clearness by Johnston² and Stieglitz³ in the papers noted in the bibliography below. Their conclusions are summarized in strikingly clear form by Bjerrum and Gjaldbaek⁴ in the expression $[H^+] = K\sqrt{P \times [Ca^{++}]}$. This formula holds for all waters which are at one and the same time in equilibrium both with calcite and with the partial pressure P of CO_2 in the atmosphere. Collins⁵ has shown that this is the case approximately with the majority of our natural waters. In those waters which are not yet in equilibrium the general trend is in that direction. In the remarks to follow we shall confine ourselves to the consideration of those waters which approximate equilibrium with calcite and atmosphere.

The value of K varies only with the temperature. At any given temperature, therefore, the equilibrium value of $[H^+]$ varies directly as the square root of the concentration of the calcium-ion and as the square root of the partial pressure of CO_2 in the atmosphere. Under particular conditions, it appears that, to all intents and purposes, K is a constant. The reactions, however, which bring about and constitute equilibrium are numerous and are subject to minor local disturbances and some of them may require many hours for completion. The natural result of such a condition is that

in practice the p_H value of a water as a rule is found to be oscillating gently in the neighborhood of the equilibrium point, much as a tree is swayed by the wind or as a boat moored in a tideway. When subjected to violent alteration—as for example by filtration—it returns slowly toward the equilibrium. In a similar manner biological concentration above a certain critical limit is able to effect a semi-permanent change in $[H^+]$ which may last even for months. Eventually, however, if isolated, the biological concentration falls and the p_H value returns to the equilibrium.

In the foregoing statements no mention has been made of the effect of temperature, which is, under natural conditions, considerable. The constant K is built up from five other constants. It has a marked temperature coefficient; becoming greater as the temperature falls. Bjerrum and Gjaldbaek⁴ give the value of -5.2 for $\log K$ at 18 deg. C. It would be decidedly helpful if determinations of the value of K were available through the range from 0 deg. to 100 deg. C., since the considerable changes which the value of K undergoes by reason of temperature variation would shed much light on many natural processes which are now relatively inexplicable.

ACTUAL OBSERVATIONS OF p_H VALUES

p_H and Temperature. Beginning in August, 1920, daily determinations of the reaction of Lake Ontario water have been carried out for a period of eleven months. During this time approximately 4,400 tests were made at various stations and at different intervals of time. In the absence of electrometric apparatus, the following procedure was adopted: To 100 c.c. of a sample of water there was added 0.5 c.c. of a 0.5 per cent solution of phenolphthalein. The reactions are reported according to the following arbitrary scale of numbers, the p_H equivalents of which it is hoped to determine later.

Reaction No.	Description	p_H Equivalent (Provisional Estimate)
0	Indistinguishable from water.....	7.8
5	Indistinguishable without comparison tube.....	8.0
10	Faintly alkaline.....	8.2
15	Alkaline.....	8.4
20	Strongly alkaline.....	8.6
25	Very strongly alkaline.....	8.8
30	Intensely alkaline.....	9.0

The first determinations in each instance were made upon a fresh sample of water, and subsequent readings were taken upon standing in the laboratory for 24, 48, 72 and, at times, 96 hours. The importance of these series of readings will be discussed at greater length later.

In view of the manner in which the above determinations have been obtained (the only method available under the local conditions), the authors expressly disclaim any pretension to "absolute-value" accuracy. It is certainly justifiable, however, to make strong claim

*Maryland State Department of Health.

†Toronto Water Filtration Plant.

FIG. 1 DAILY OBSERVATIONS
OF REACTION AND
TEMPERATURE OF
RAW WATER

to "relative-value" accuracy so far as the conditions of the experiments go and because of the care taken in carrying out the tests. In each instance the test tube used was rinsed, brushed and soaked for some time with fairly strong HCl, to prevent after-effects due to solution of glass with resultant increase in alkalinity of the liquid tested. After soaking, the tube is again well-rinsed, brushed twice with complete rinsing following each brush, and then rinsed three times with distilled water. This procedure is followed by three washes with the water to be tested, after which the tube is filled to the mark.

In Fig. 1 there have been plotted the daily readings, for eleven months, of the temperature and the p_H of the waters at a certain intake on Lake Ontario, which supplies a mechanical filtration plant. A similar series of readings at a neighboring intake, furnishing a slow-sand plant, are not plotted, since they differ only slightly from those used. It is at once apparent from the data in Fig. 1 that the reaction of the raw water is continually fluctuating in accordance with the water temperature. The striking fact appears that the p_H values show marked seasonal as well as daily changes, which in turn are influenced in a secondary manner by biological contamination. It is important to call attention to the fact that in most instances these delicate fluctuations in reaction are not reflected in the usual titration measurements for alkalinity.

p_H and Filtration. In order to study the changes which such processes as alum addition and rapid filtration effect in reaction of water, daily determinations

were carried out upon the effluents of a mechanical filtration plant from August, 1920, to June 26, 1921. Only two months' observations are shown on Fig. 2, since these are characteristic of the summer and winter conditions as indicated by all the tests. It is apparent that the combination of alum treatment and filtration causes striking changes in p_H conditions. The fact that filtration alone is responsible for major effects is further illustrated by data shown in Fig. 3, where a comparison is presented between reactions of slow-sand as against those of rapid-sand filter effluents. It is well to bear in mind that such upheavals as filtration alone may occasion as profound changes in the equilibria of waters as do the more familiar chemical processes, as alum treatment.

It is true, of course, that such changes in reaction as have been indicated above are only semi-permanent in character, but they are of sufficiently long duration to make their effect of prime importance. Although adjustments are continually in process, the periods of time necessary to reach complete equilibrium, after such cataclysmic disturbances as filtration, may stretch into three or four days. These phenomena of internal adjustment in reaction are well brought out in another series of selected readings in Fig. 4, which represent only a few of hundreds of similar tests during summer and winter conditions.

The significance of the data shown on Fig. 2 will be even more striking when it is noted that the most effective filtration, from the standpoint of removal of bacteria and suspended matter, is accomplished usually

at those times when the reaction of the filtered water is in the neighborhood of 0 to 2 on the particular scale used in these tests. It is certainly of great importance to emphasize this observation, since therein lies probably one of the least known and most crucial regulating factors of filtration—namely, the reaction of the liquid filtered. We call attention especially to this particular phenomenon, in view of the fact that hitherto little attention has been paid in the interpretation of filtration experiment to the reaction of the water under study. The standardization of rates of filtration, of depths of sand beds and of sizes of sand grains have been determined in most instances without reference to the reactions and electrical signs of either the water or the materials suspended therein. In this connection it need only be recalled that many substances when suspended in water become negatively charged, with the intensity of the charge increasing when the concentration of the hydroxyl-ion becomes greater. In particular, clay particles and bacteria are usually negative, while it is believed that alumina used for mechanical filtration is negative when the p_H of the solution is greater than 7.5 (Sørensen's scale). Naturally the negative charges of such substances are influenced greatly when the H-ion concentration is increased or lowered. Because of these influences, it is possible to see why reaction should control, to a degree, both rate and efficiency of filtration.

The importance of the reaction of the medium being filtered has been amply demonstrated in another field

In fact, Holderer concludes from his series of observations on filtration of finely divided particles, comparable in size with bacteria usually found in water, that the reaction of the liquid filtered is of prime importance. His process of reasoning, based on his experimental results carried out with care, may be briefly summarized as follows: The volume of granules is very variable and is especially a function of the reaction of the medium. One ought, therefore, to take account of this reaction, all the more because upon it depend the sign and the size of the electrical charge. Perrin has shown in effect that every membrane in contact

FIG. 3. COMPARATIVE EFFECTS OF RAPID AND SLOW SAND FILTRATION ON REACTION OF RAW WATER

with an alkaline solution is charged with negative electricity. If the solution is acid, the membrane is positive. Quincke further demonstrates that if we cause alkaline water to pass through a capillary tube, or a filter of sand or of gelatine, we obtain the positive charge of the water toward the outlet, while at the entrance the negative electricity has accumulated. These two charges, positive and negative at outlet and inlet, constitute an electromotive force of filtration opposing the movement of liquid.

Since we have already seen that the size of the particles is primarily a function of the reaction of the medium, there is nothing astonishing therefore that, from the point of view of speed of filtration, it is again the reaction of the liquid which is most important. This conception is further supported by evidence accumulated to show that the adsorption effects in filtration are also dependent upon the reaction of the medium and of the polyvalent coagulating ions.

THE NATURE OF FILTRATION

One cannot refrain, on account of the excellence of the reasoning, from quoting further from the thesis by Holderer, on the question of the nature of filtration:

"By what mechanism is the retention of enzymes brought about? Is it a sort of entrapping or a phenomenon of attraction? The study of the influence of coagulating and dispersing agents, such as albumin, has made it possible for me to conclude that it is particularly a phenomenon of adsorption—that is to say, by attraction primarily. Yet for enzymes poorly dissolved or which are in a state of partial coagulation, it is evident that we have a phenomenon of entrapping.

"One cannot attribute the retention of sucrase on the filter to an impoverishment of salts, for the addi-

FIG. 2. EFFECT OF RAPID SAND FILTRATION AND ALUM TREATMENT ON REACTION OF RAW WATER

of scientific investigation by Holderer⁶ in a masterly thesis, which should be more familiar to waterworks men. Holderer, in his experiments on the filtration of enzymes, obtains the following characteristic results:

Reaction of Liquid	Per Cent Removal of Enzymes by Filtration
a. Neutral to phenolphthalein	0
b. Neutral to methyl orange	96
c. Intermediate reaction	75

It is clear from the data shown above, which are typical of those found in the filtration of numerous other finely suspended or colloidal materials, that the reaction of the medium being filtered is fundamentally the controlling mechanism of the success or failure of filtration.

tion to the filtrate of all the salts of the original solution produces no activation.

"Sucrase is retained therefore by adsorption and not by entrapping. It is the most frequent case. Enzymes act like bacteria. Duclaux in fact has already noted the force of adhesion which retains bacteria. 'From the standpoint of the average dimension of spores,' he said, 'the pores of the most porous substance are as tunnels toward wagons.'" Holderer further points out that "the spores of *Aspergillus niger* are retained by simple filtration through paper in a reaction neutral to methyl-orange, while at neutrality to phenolphthalein they pass through the filter paper. This remark suggests the thought of a work similar to this upon the question of the filterability of bacteria at various reactions."

Unfortunately the authors have been unable to find any further research along the lines suggested above, but it certainly appears from the data which Holderer has set forth, from the recent work on the filter-pressing of sewage sludge by Wilson, Copeland and Heisig⁷ and from the observations reported in this paper by the present authors, that important results would probably appear if new studies were carried out upon the entire problem of the mechanism of water filtration from the standpoint referred to above. It is not too optimistic to suggest that in such studies it may even be found that a considerable revision of our present concepts of the importance of definite gra-

dation of size of sand and of definite rates of filtration may be necessary.

In a similar manner, as has already been pointed out by the writer,¹ much fruitful research is possible in the field of precipitation and sedimentation of suspended particles, where the forces of electrical repulsion and of molecular attraction come into play. The solution of the problems arising in this field do not differ in method from those which appear in filtration. For the sand filter itself has the character of a charged membrane, the variations in whose charge may tend materially to promote or to retard the rate and efficiency of filtration.

p_H and Chlorination. Some reference should be made, if only briefly, to the possible significance of reaction of water in processes of disinfection with chlorine or its derivatives. Insufficient material is available upon which to draw any conclusions at this time. It is known, however, that the efficiency of such processes varies from season to season and even from hour to hour, but only the elementary causes of such variations are understood. For this reason, the recent studies reported upon by Rideal and Evans⁸ are of special importance. They recognize that hypochlorites, for instance, are usually applied to waters "irrespective of whether the fluid be acid, neutral or alkaline." Their preliminary conclusions are peculiarly interesting in connection with the figures reported upon in this paper. Several excerpts from the work of Rideal and Evans⁸ are, therefore, noted here for emphasis:

RIDEAL AND EVANS' CONCLUSIONS

"We find that two waters, one an 'acid' water containing free carbon dioxide and the other an 'alkaline' water, such as occurs in the London basin, dosed with hypochlorite so that they contain the same amount of 'available chlorine' (as measured by the ordinary iodometric method with titration in presence of acetic acid), give quite different results when allowed to flow through the electrical instrument. The acid water gives a large deflection, indicating high oxidizing activity; the alkaline water gives a much smaller deflection, indicating that the oxidation potential has been depressed.

"Since the germicidal properties . . . are in part due to its oxidizing power, it seems likely that these also will be affected by the hydrogen-ion concentration of the water. It would be worth while, therefore, to consider whether, if alkaline waters have to be treated with this class of sterilizer, they should not at the same time be rendered just acid to litmus, or at least neutral, by the addition of niter cake, aluminum sulphate or even by treatment with carbon dioxide gas."

TEMPERATURE, REACTION AND FILTRATION

If the data presented above are valid, what effect may we be led to expect in such processes as sand filtration from season to season? Theory would certainly indicate that it should be more difficult to get good results from our filters in the warmer months, when the *p_H* is higher. In actual practice, this is frequently the case, but it is sometimes ascribed to "colloidal difficulties." Its obvious remedy should be an increased dose of alum, which will result in a reduction of *p_H* to the point of improved operation. In calculating such dosages of chemical, we should not lose sight of the fact that the initial CO₂ content of the water, as well as that lost to the atmosphere in such processes as mixing, are controlling factors no less than the alumi-

FIG. 4. TREND OF REACTION OF WATERS TOWARD EQUILIBRIUM

num sulphate used. In other words, the floc-forming power of alum has frequently overshadowed its CO_2 productivity. The latter may be the more important regulating mechanism of precipitation and filtration.

Evidence confirmatory of the hypothesis that efficiency of filtration and coagulation processes vary inversely with p_H is given by the data presented in an excellent paper by Jordan.⁹ The latter clearly points out that filtration, taken as a whole, falls off in effectiveness as the temperature rises, a phenomenon which Jordan associates with increased biological activity. But biological activity is actuated by such mechanisms as osmotic pressure across the membranes, which pressures Loeb¹⁰ has shown vary with potential difference and with p_H . Since temperature, p_H and biological activity are correlated phenomena, p_H again is the significant explanatory index to seasonal variation in filter efficiency.

CORRELATED PHENOMENA

The opportunity should be taken at this point to indicate the fact that the temperature-reaction phenomena discussed above may have important applications to problems not specifically mentioned in this paper. The principles outlined herein should have far-reaching effects in clarifying some of the concepts in the fields of botany, zoology and physiology. It is not, of course, within the scope of this paper to go into the details of the problems in these fields, but a sufficient number of pertinent facts have appeared in our researches to indicate the importance of the data herein presented to the other branches of science. The workers with soils, plants and animals will no doubt be able to adapt some of the findings to their own problems.

Decline of the Sicilian Sulphur Industry

Until recent years Sicily was the most important factor in the world's supply of sulphur, but it has now been displaced by the American sulphur industry, which has developed a very large production owing to the easy extraction of this mineral from the Louisiana and Texas mines, declares Consul Louis G. Dreyfus, Jr., of Palermo, Italy, in *Commerce Reports*.

The production of sulphur in Sicily rose from 120,000 tons in 1860 to 538,534 tons in 1905. In 1919 production decreased to 181,374 tons, but rose to 219,844 tons in 1920. On the other hand, the production of American sulphur increased from 893 long tons in 1883 to 25,000 tons in 1903 and 491,080 tons in 1913, and reached 1,255,249 long tons (preliminary figures of the United States Geological Survey) in 1920. Besides these two countries, Japan, with an output of about 50,000 tons, is the only other important source of sulphur. Small quantities are produced in Spain and Austria.

During the war sulphur, which was required for the production of ammunition, was in great demand, but owing to the lack of tonnage the shipment of American sulphur to Europe was interrupted. The Italian Government commandeered the sulphur trade, authorizing exportation only with special permits. Now that freights are again normal, American sulphur exporters are everywhere underbidding the Sicilian product. In fact, the American quotation c.i.f. Hamburg, delivery weight, was at the beginning of June, 1921, 1,320 marks, while Sicily was quoted about 3,000 marks. The Sicilian product has been completely displaced in the important Scandinavian markets and is facing keen competition in Belgium, England, the Netherlands, France, Germany and Africa.

It is said that American sulphur is superior to the Sicilian for the chemical industries. However, the latter is preferred locally for the vineyards, where it is used to protect the foliage against parasites, because it is said the flour-milled product from the United States does not adhere to the leaf to the same extent as does the Sicilian. Partly for this reason and partly because of their geographic location France, Spain, Portugal, Algeria and Greece still look to Sicily for sulphur to be used in their vineyards.

Statistics of the Canadian Soap Industry

Canada spends in the neighborhood of \$14,000,000 a year on soap, according to a recent report of the Dominion Bureau of Statistics relating to the manufacture of soap in Canada during 1918.

Thirteen of the twenty-eight plants engaged in this industry are located in Ontario. During the year reported over 100,000,000 lb. of soap was manufactured in Canada and the quantity sold by the producers was worth over \$13,000,000. In addition to this there was imported into Canada something over \$1,000,000 worth of soap produced in other countries.

The report states that exports of soaps amounted to only slightly over \$100,000. There is thus an apparent opportunity for the expansion of the soap industry in the country to take care of the million dollar importation which now exists. It is stated that the bulk of the imported soap is of the common or laundry variety, there being 5,000,000 lb. of this soap imported during the year under review. Over 800,000 lb. of soap powders was also brought in. The quantity of toilet soap imported is not stated, but the value was \$592,000.

Melting Fine and Sterling Silver by Electricity

A Description of the Operating Conditions for Melting Fine and Sterling Silver in an Electric Furnace—Arrangement of a Silver Melting Outfit—Comparison of the Qualities of Electric and Crucible Silver

BY H. A. DE FRIES
Consulting Engineer

THE writer lately had the opportunity to conduct the melting of fine and sterling silver on a large scale in an electric furnace. In the following will be enumerated the principal points which have to be taken into consideration for such melting:

It is generally surmised that a pouring temperature of 1,900 to 2,000 deg. F. (about 1,040 to 1,095 deg. C.) is sufficient. This degree of heat will suffice if the silver is cast into bars for remelting. If one, however, endeavors to pour silver at this temperature into rolling stock or castings, the resulting metal would be so brittle as to be entirely worthless for subsequent working. The proper temperature at which such silver should be cast is 2,360 to 2,380 deg. F. (about 1,295 to 1,305 deg. C.) if cast into horizontal or nearly horizontal molds, or 2,200 deg. F. (about 1,205 deg. C.) when vertical molds are used. Utmost care has to be exercised in handling the molten metal between furnace and molds, and any chilling should be prevented as much as possible, as a difference of only 200 deg. F. will produce crystallization with attending brittleness. During melting the silver should remain quiet and the bath should not be disturbed by stirring or rocking.

AFFINITY OF SILVER FOR GASES

It seems that during melting a protective cover is formed, which protects the silver from gases. It is well known that silver has a great affinity for gases, especially oxygen, and if this cover is disturbed by stirring, etc., unprotected silver is brought into contact with the furnace gases and entering air, which will be absorbed at once.

Notwithstanding that fine silver is supposed to liberate most occluded gases by spitting on cooling, enough will remain, even though in very small quantities, to have a decided influence on the structure and ductility of the resulting metal.

How susceptible silver is to gases is best illustrated by melting it in an oil-fired crucible. In such operation a marked difference in quality of the metal will be apparent when using oils of varying analyses; even a change in the barometric pressure of the air used for combustion will be immediately noticeable.

As the atmosphere in an electric furnace is independent of outside conditions and can be changed at will, an absolute oxygen control is made possible, and this is of the greatest advantage. In practice it was found that an almost neutral atmosphere, tending toward being slightly reducing, is most suitable. This atmosphere can be easily obtained in an arc furnace and the carbon supplied by the electrodes is in most cases sufficient.

If a more reducing atmosphere is required, some charcoal may be added after the silver is molten. Pow-

dered coal in quantities not exceeding 1 lb. per 5,000 oz. of silver will be found most effective. It is evident that the furnace itself should be airtight and if an arc furnace is used stuffing boxes should be provided at the electrode ports. Pouring the charge through the furnace door will not do, if the door has to be open during pouring. It is much better to pour the silver through a separate taphole, which can be lined and kept closed by a plug made from an electrode stump.

The travel of the metal from spout to mold should be as short as possible. With proper arrangements the writer has experienced no trouble from skin forming during pouring. If an intermediate receptacle is used between spout and mold, it should be thoroughly preheated. Any metal left in this receptacle should be poured out and no new metal should be poured on top of it. The molds should be smoked and heated to about 400 deg. F. (about 205 deg. C.).

In making rolling silver, the time-honored method of having a piece of wrought iron or mild steel in the bottom of the hearth should be adhered to, as it will be a great help in keeping a low oxygen equilibrium in the metal, and at the same time this piece of iron will act as a stabilizer for the heat of the silver.

In starting up a new furnace the operator may not be able to judge the right pouring temperature from the appearance of the metal, and until he becomes familiar with it he should resort to the well-known pouring and annealing tests.

ELIMINATION OF IMPURITIES

The impurities in silver, especially if old metal and scrap are remelted, will be mostly in such small quantities as to be but a fraction of a per cent; in most cases the impurities are due to small quantities of german silver. Two methods can be used of partly eliminating the impurities in the furnace—i.e., by either slagging them off or by removal through cupellation. The second method is the one most commonly employed in arc furnaces. When using this method the electrodes are to be brought almost in contact with the bare bath and the furnace run slightly oxidizing for a short period.

FURNACES USED

After having thus discussed the principal necessities for the electric melting of silver, it is apparent that only two types of furnaces can come into consideration—i.e., the indirect arc furnace of the stationary type and a certain type of induction furnace, such as the Ajax-Northrup. The indirect arc furnace seems to possess greater adaptability to this work than the Ajax-Northrup, and this is especially true in regard to capacity.

The furnace the writer used during his silver runs was of the Rennerfelt type, especially constructed for the purpose and of 10,000-oz. capacity. The average charge was 4,000 oz. and the power consumption averaged 330 kw.-hr. per ton of silver. I understand that silver was melted in the Ajax-Northrup furnace with about 320 kw.-hr., so that it checks closely with results obtained in the Rennerfelt. Preheating is included in the figure of 330 kw.-hr.

The lining of the indirect arc furnace should be either of silica brick or firebrick, with a hearth of gannister or carborundum. This hearth material should be wetted down with silicate of soda, tightly rammed in and thoroughly sintered with the arc. The life of such a lining will be almost indefinite.

The determination of the metal loss was not quite conclusive, but on the average it amounted to about 2 oz. per 1,000 oz. melted. Some silver will always be absorbed in any newly lined furnace, and after the furnace has been in use a little longer I feel confident that silver can be melted in electric furnaces with a total loss not exceeding 5 oz. per 10,000 oz. melted. The electrode consumption will average about 5 lb. per ton.

The furnace will produce about 60,000 oz. of silver per eight hours and the cost of melting and casting 1,000 oz. into rolling ingots will be as follows:

Loss, 0.5 oz. per 1,000 oz.....	\$0.25
Power, 12 kw.-hr. at 2c.....	.24
Labor, melting and pouring.....	.20
Charcoal, at 2c. per lb.....	.0025
Electrodes.....	.05
Refractories.....	.01
Heating ladle and molds.....	.02
Total.....	\$0.7725

ARRANGEMENT OF A SILVER-MELTING OUTFIT

As previously intimated, the handling of the metal after it comes from the furnace is of just as much importance as the melting itself, and the writer herewith will give a design¹ as to how an efficient silver-melting outfit should be constructed:

A is a lip-tilting electric furnace which is charged through door B. A special lined taphole and spout are placed directly beneath the charging door. During pouring the door remains closed and the metal flows through the taphole into a lined pot or crucible hung in front of the furnace. The crucible or pot is provided with a cover and sets into a ring so that the

¹Patent applied for.

CONSTRUCTION OF SILVER-MELTING OUTFIT

entire pot is removable. Before using it should be thoroughly preheated and it should be of sufficient capacity to hold enough metal to fill one or more molds. The pot is also lip-tilting and is worked with a lever. In front of this pot runs the mold car, provided with a deck which can be moved back and forth by a lever. Under the lip of the mold car is placed a spillpan, into which also is poured any surplus metal from the pot.

As mentioned before, it will not do to leave any metal in the pot and pour new metal on top of it. If insufficient metal is left in the pot to complete a mold, it should be poured into the spillpan and remelted afterward.

The operation of this equipment is very simple and the operator will get used to it very quickly.

COMPARISON OF ELECTRIC AND CRUCIBLE SILVER

Comparing now the quality of the electric silver produced by this method with standard-grade crucible silver, we get some very interesting figures. The electric silver and the crucible silver were submitted to various tests with the following results:

I. *Fracture*. Electric silver of much finer grain than crucible silver.

II. *Rolling*. Electric silver easier to roll.

III. *Stamping*. Electric silver stamped perfectly.

IV. *Deep Forging*. Extreme test; 100 per cent sound forgings from electric silver against 15 per cent from crucible silver.

V. *Spinning*. On the same extreme long draw, crucible silver failed completely, whereas electric silver came out 100 per cent perfect.

Magnesium Carbonate in the Glue Industry

Light carbonate of magnesia is a material which should be of interest to manufacturers of glues and mucilages, since it is of value as an opaquing agent. For such a use there is required a finely-divided, white, inert pigment, and magnesium carbonate has been shown, by a preliminary investigation at the Mellon Institute of Industrial Research, to meet these requirements. The material has a decided cost advantage over zinc oxide used for the same purpose, owing to the fact that it has a specific gravity of only 2.2, as compared to 5.78 for zinc oxide. Since the opaquing or pigmenting effect is determined on a volume basis, both the zinc oxide and magnesium carbonate being insoluble in the material in which they are suspended, the magnesium carbonate would be about one-third as expensive to use as zinc oxide, where the price of these two materials is the same per pound. The low specific gravity and bulky crystalline form of magnesium carbonate cause it to settle very slowly when suspended in a viscous material while zinc oxide, having much higher specific gravity and being more compact in the form of its particles, will not remain suspended so long.

Glues from different materials vary so in composition that it will be necessary to study the effect of each glue on this pigment, owing to the fact that in certain cases impurities may cause agglomeration and rapid settling of the pigment. Magnesium carbonate is basic in character and will, of course, be dissolved by large percentages of acid in glue, but the same is true of zinc oxide. Further information with regard to this material may be obtained by addressing the Director of the Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa.

A Discussion of the Slip Interference Theory of Hardening

Professor Sauveur Is Prepared to Accept the Idea That Martensite Contains Alpha Iron, but Wishes More Evidence on the Contention That Its Hardness Is Due to Sub-Microscopic Grain Size, and That Cementite in Solid Solution Is Dissociated

By ALBERT SAUVEUR
Professor of Metallurgy, Harvard University

IRON containing a sufficient proportion of carbon, cooled with sufficient rapidity from a sufficiently high temperature, increases intensely in hardness. No such increase in hardness resulting from like treatment has ever been observed in any other metal or alloy. Strenuous efforts, experimental and mental, have been exerted by several generations of metallurgists to explain so important and unique a phenomenon. The metallurgical world was for a long period of time satisfied with the vague statement that quenched steel was hard because of the presence of "hardening" carbon, although at an early date the possible influence of severe internal strains was recognized. For a full score of years—namely, from about 1895 to about 1915—various theories were proposed to explain the hardening of steel, their discussion at times being conducted with considerable heat. By some the problem was taken from the domain of the laboratory to the quiet of the study, and several "desk" theories were added to those already under consideration. Activity in this field of research dates back to Osmond's epochal discovery of the allotropic transformations of iron and was further kindled by metallographic progress and by the application of the phase rule of Gibbs to metallic alloys. The theories that have been discussed include the "beta iron theory" of Osmond, the "alpha iron-solid solution theory" of Henry Le Chatelier, the "amorphous iron theory" of Humfrey, the "sub-carbide theory" of Arnold, the "stress theory" of André Le Chatelier, the "interstrain theory" of McCance and the "twinning and amorphous iron theory" of Carpenter and Edwards.

APPARENT STALEMATE

In 1915, summing up a short discussion of these theories, I ventured the following remarks: "It would seem as if the methods used to date for the elucidation of this complex problem have yielded all they are capable of yielding and that further straining of these methods will only serve to confuse the issue, a point having been reached when this juggling, no matter how skillfully done, with allotropy, solid solutions and strains is causing weariness without advancing the solution of the problem. The tendency of late has been to abandon the safer road of experimental facts and to enter the maze of excessive speculation, in which there is great danger of some becoming hopelessly lost. The conclusion seems warranted that new avenues of approach must be found if we are ever to obtain the correct answer to this apparent enigma."

The following remarks of Portevin and Garvin¹ are also to the point: "It is needful to guard against hypotheses which depend on the effect of an immeasurable quantity, as there is always a temptation to attribute to it values favoring *a priori* conception, and

to give to a *petitio principii* the appearance of a demonstration. It is from such methods of reasoning that the interminable disputes relating to theories of quenching have arisen, which have no likelihood of ending so long as they rest on such foundations."

The relative calm which for the last five or six years has prevailed in a previously turbulent sea has been brought to an end by the presentation of a new theory of hardening by Dr. Zay Jeffries and R. S. Archer, called by them the "slip interference theory."

The temptation is very great, and the danger also, to accept the authors' new theory, to declare the problem solved and to turn one's attention to others still unsolved and less elusive. O that this could be done! Any pretence, however, at scientific thinking carries with it its obligations, and one is compelled before accepting the newcomer to examine him critically to ascertain whether he is in reality a more sturdy and promising youth than his older brothers.

I desire at the outset to express my admiration for the mastery and skill with which the authors present their theory. Theirs is a brilliant thesis which discloses their erudition and scientific acumen.

OUTLINE OF THE NEW THEORY

The authors define hardness as "resistance to permanent deformation," which in turn results from the attractive forces between their atoms or interatomic "bonds." To deform the metal permanently we must break up some of the interatomic bonds. This definition of hardness can be accepted as accurate, although it would serve as well as a definition of elastic limit and although of two metals the one having the higher elastic limit has not necessarily the greater hardness.

The authors state that increased hardness implies increased resistance to slip, or "increased slip interference." Since it is generally accepted as proved that when a metal or alloy made up of crystalline constituents is permanently deformed, the deformation results from slips having taken place along some planes of weakness of the crystal which may be cleavage planes, it necessarily follows that increased hardness (since it means increased resistance to permanent deformation) results from greater resistance to slip—i.e., to greater "slip interference"—and that any factor tending to produce greater "slip interference" increases the hardness of the metal. The proposition is not of course applicable only to the authors' theory; on the contrary, it fits in with any theory of hardening, since it is based on the definition of hardness and on the manner in which crystalline metals yield on being permanently deformed.

The following factors, according to the authors, may be considered as increasing slip interference and therefore increasing hardness: (1) Boundaries of crystalline

¹Iron and Steel Institute, May, 1919.

grains—from which it would follow that the smaller the grain the harder the metal, since a smaller grain implies a greater number of boundaries; (2) possible presence of amorphous metal at the boundaries, intensifying their slip interference action; (3) the slip bands themselves, from which it follows that a metal increases in hardness on being permanently deformed; (4) the possible presence of amorphous metal at the slip planes, intensifying their slip interference action; (5) twin crystals—by opposing slip propagation in the crystal in which they occur; (6) the presence of foreign particles acting as “keys” in obstructing slip, an action which is the more marked the smaller the particles and the greater their number, this rule, according to the authors, reaching its limit as the particles approach atomic dimensions, and the hardening effect being maximum for what they term “critical dispersion.”

NATURE OF MARTENSITE MUST BE ADEQUATELY SET FORTH

The authors attribute the hardness of quenched steel to the hardness of martensite. This statement can be accepted without discussion. Any theory of hardening necessarily makes the same claim. It is only in regard to the nature of martensite that they differ. Martensite is claimed by the authors to be a solid solution. The same claim has been made before by others. Many have believed with Osmond that martensite is a solid solution of carbon or of the carbide Fe_3C in beta iron, while others prefer with Le Chatelier to consider it as a solid solution of carbon or the carbide in alpha iron. Again, those who, like McCance, Carpenter and Edwards, are inclined to attribute the hardness of quenched steel to “interstrain,” to twinning or to the presence of amorphous metal also consider martensite as a solid solution. The belief, therefore, that martensite is a solid solution is quite general and has been held for a long time.

Of necessity martensite must be (1) a definite chemical compound, (2) an aggregate, or (3) a solid solution. That it is a definite chemical compound, Fe_3C , containing iron in solution in hypo-eutectoid steel and Fe_3C in hyper-eutectoid steel, has been maintained by Arnold. The improbability of this hypothesis is so great that it may be dismissed without reviewing the arguments that have been so often offered in opposition. To decide whether martensite is a solid solution or an aggregate we naturally turn to the microscope, because we know what should be the appearance of a solid solution. We have been told and have frequently observed that solid solutions are made up of polyhedral crystalline grains corresponding to so-called “network” structures in polished plane surfaces. We fail, however, to observe under the microscope any such structure. Instead we discover that martensite has an “acicular” structure and we are unable to detect any suggestion of the existence of polyhedral grains. Our first impulse, therefore, would be to conclude that martensite is not a solution. The improbability of its being an aggregate, however, is so great that in spite of its structure we are reluctant to abandon the view that it is a solid solution and we try to find a satisfactory explanation for its acicular aspect. Carpenter and Edwards, for instance, contend that the “needles” of martensite correspond to austenite twins caused by the internal straining of the metal during quenching.

The authors of the theory under discussion express their belief that grains of martensite exist but that

they are sub-microscopic—that is, too small to be observed under the microscope. Indeed they consider this extremely small size of the grains of martensite to be the chief cause of its hardness. I do not understand that they offer any explanation of its acicular appearance.

While not denying that the weight of evidence supports the contention that martensite is a solid solution, it should be borne in mind that the conclusion rests on a process of elimination—that is, on our justified unwillingness to consider it an aggregate or a definite chemical compound—rather than on direct proofs, and furthermore, that it is not supported by the appearance of martensite under the microscope.

MUST A COMPOUND DISSOCIATE ON ENTERING SOLID SOLUTION?

The authors argue that a metal holding another metal or metalloid in solid solution is harder than the pure metal. They write: “It is a general rule that metals are hardened and strengthened by the addition of elements which dissolve in them to form solid solutions.” This they explain on the ground that intermetallic compounds are not dissolved as such in solid solution, but first must be dissociated to be held subsequently in solution in “atomic dispersion.” To clarify: The definite intermetallic chemical compound $\text{M}_x\text{M}'_y$ of two metals M and M' cannot form a solid solution with either of the metals; it is the metal M' in its elementary state that is dissolved in M, or *vice versa*. “The increased hardness and strength,” they write, “are therefore traceable directly to increased interatomic forces, the attraction between unlike atoms being in general greater than between like atoms.”

In order to follow the authors' demonstration of their theory, therefore, it is necessary to accept their views, (1) that an intermetallic compound cannot be held in solid solution in a metal and (2) that interatomic bonds between unlike atoms are stronger than between like atoms. In support of their first contention we are told that intermetallic compounds could not, because of their size, diffuse through the solvent metal. Applying this view to the solid solution of carbon in iron, they write: “Diffusion must consist in a migration of carbon atoms and not of groups or ‘molecules’ containing several iron atoms. Such groups could not, on account of their size, diffuse through solid iron.”

While not in a position to deny such claims, I believe that others will agree with me that before accepting as a demonstrated fact that intermetallic compounds cannot exist in a state of solid solution in a metal, more conclusive evidence should be forthcoming. The question is too important to be considered settled by the single argument of the authors. Their claim leads to many deductions requiring explanations. To mention but one: It is fairly conclusively established that silicon is present in iron as the silicide FeSi and it was generally believed that this compound was held in solid solution by the iron. According to the authors' view, however, this could not be; the compound must first be dissociated and silicon must be present in atomic dispersion. The silicide is, however, found in the steel at room temperature. When then did it form and where the evolution of heat that should accompany its formation? Such examples could be multiplied.

In regard to the statement that interatomic bonds between unlike atoms is greater than the bonds between like atoms, from which it follows that solid solutions

must be harder than the solvent metal, supporting evidences should be offered. If physical chemists have demonstrated this to their satisfaction, their proof should be given or at least the reader should be given the necessary references.

THE IRON OF MARTENSITE IS ADMITTED TO BE IN THE ALPHA MODIFICATION

The authors' theory, therefore, postulates as demonstrated facts, (1) that martensite is a solid solution, (2) that in martensite carbon in its elementary form and not the carbide Fe_3C is dissolved in iron, and (3) that solid solutions are harder than the solvent metal because of the greater interatomic bonds existing between unlike atoms, from which it follows that martensite must be harder than iron. We are justified, I believe, in accepting these conclusions with some reservation, especially in regard to claim 2.

We are further told by the authors that iron in martensite is present in its alpha form. This has long been the contention of Le Chatelier and of some other metallurgists. The additional evidence offered by the authors in support of this view is stated by them as follows:

"The X-ray spectrometer proves that alpha iron is the chief constituent of martensite. Steels which are non-magnetic show face-centered cubic lattices with the X-ray spectrometer, whereas martensite, which is magnetic, shows a body-centered cubic lattice. A 1.5 per cent carbon steel quenched from above the critical in iced brine showed both martensite and austenite under the microscope, and the X-ray spectrometer pattern showed both face- and body-centered lattices. A 0.35 per cent C steel quenched from above A_c , showed only martensite under the microscope and only a body-centered lattice with the X-ray spectrometer."

This proof of the presence of alpha iron in martensite and of the absence of gamma iron is considered definite and final by the authors. The conclusiveness of the evidence depends altogether upon the faith we have in the results yielded by the X-ray spectrometer.

I am not in a position to take issue on this point with the authors, nor do I desire it—on the contrary, I am quite prepared to accept the correctness of their view.

JEFFRIES AND ARCHER'S VIEW OF MARTENSITE

Admitting then that martensite is a solid solution of elementary carbon in alpha iron and that because it is a solid solution it must be harder than pure iron, we are told that this is only a contributory and relatively unimportant cause of its hardness—that its extreme hardness is due primarily to the *size* of its grains, which are described as "sub-microscopic." We naturally infer that if pure iron could be obtained in sub-microscopic grains it would be quite as hard as quenched steel.

To account for the formation of these sub-microscopic grains the authors argue that when austenite is transformed into pearlite at its normal critical temperature, two distinct transformations take place: (1) the allotropic transformation of gamma into alpha iron, followed by (2) the combination of carbon with alpha iron to form Fe_3C . They write: "The latter would not form unless the iron changed its crystal structure. Therefore the allotropic transformation of the iron is the cause and the formation of cementite is the result. . . . When austenite is slowly cooled through A_1 , the two changes occur so close one after another as to be called simultaneous. . . . When the cooling rate of the austenite

is sufficiently rapid to form martensite, the transformation of the gamma iron to alpha is substantially complete, whereas the formation of cementite is not complete. Martensite should therefore consist principally of sub-microscopic ferrite grains containing carbon in solution. . . . Although the ferrite of the martensite is held to contain carbon in solution, it is considered that the fineness of grain is chiefly responsible for the hardness." And again: "The hardness of martensite may therefore be attributed chiefly to a combination of two factors—namely (1) the super-refinement of the ferrite grains, and (2) the strengthening of ferrite by carbon."

The authors' theory therefore rests on the formation of sub-microscopic grains on quenching steel, and the following reasons are given by them in support of their contention:

"1. The conditions obtaining at the time of the formation of martensite are conducive to the production of small grains.

"2. In low-carbon martensite formed from coarse-grained austenite, ferrite can often be seen under the microscope in the form of very small plates.

"3. In higher carbon steels which are conducive to the formation of finer grains on quenching, no ferrite can be resolved under the microscope.

"4. In order to obtain a good Hull pattern with the X-ray spectrometer it is necessary that the specimen be fine-grained. In a 0.35 per cent C martensite, formed by quenching from 1,300 deg. C., the alpha iron pattern was typical of that obtained from fine-grained metals, even though the austenite grains from which the martensite was formed were large enough to be seen with the unaided eye."

MORE EVIDENCE NEEDED

Without any desire of being hypercritical I do not think that these reasons can be accepted as at all conclusive of the existence of sub-microscopic grains in martensite, and since they are essential to the theory proposed by the authors, it is in order that we should demand more convincing evidence.

The part played by carbon in the hardening of steel is thus described: "The presence of the carbon assists in the hardening indirectly by helping to produce a very fine ferrite grain size and directly by strengthening the ferrite grains." The authors face here the same difficulty as was encountered by their predecessors. The action of carbon is indirect, we are told—it helps in producing microscopic grains. The argument recalls the claim of the allotropists that carbon *helps* in retaining beta iron, a claim which has always been considered one of the most vulnerable points of the theory. Arnold, of course, took the bull by the horns in assuming the existence of a very hard carbide of iron (Fe_3C), but then his theory is untenable. Assuming, as we must, that carbon helps in the production of fine grains, the mechanism of the assistance rendered is not satisfactorily explained, if explained at all.

While appreciative of the talent and skill with which the authors present their theory of the hardening of steel, some of us, I believe, will hesitate to accept it as a fully satisfactory and final solution of the problem, because we are asked to accept as a demonstrated fact, without being given sufficient evidence in support of the contentions, that an intermetallic compound cannot exist in a metal in a state of solid solution, and that the carbide Fe_3C , therefore, cannot be present in solid

solution in gamma or alpha iron; because we are asked to accept as a demonstrated fact that in martensite grains of alpha ferrite exist in sub-microscopic dimensions without being given convincing evidences of that important, and to the theory essential, phenomenon; because, referring to the rôle played by carbon in the hardening of steel, we are asked to be satisfied with the rather vague statement that carbon helps in producing sub-microscopic grains without any explanation of the mechanism of this action; and because the theory does not satisfactorily explain why sub-microscopic grains and therefore hardness cannot be obtained in other metals and alloys by quenching.

We further hesitate to accept the theory as final because the authors reopen wide the doors of speculation. It might be claimed, for instance, that martensite is hard simply because it is a solid solution of alpha iron and carbon in atomic dispersion, the carbon atoms acting as "keys" (to use the author's expression), from which it would follow that the more carbon—that is, the more keys—the harder the martensite. Could not such a theory be defended vigorously and cogently? It would at least have the advantage of offering a more acceptable explanation of the need of carbon to harden steel and of the absence of hardness in the absence of carbon. This, of course, would be a return pure and simple to Le Chatelier's theory.

Legal Notes

BY WELLINGTON GUSTIN

Utzman Patents for Gypsum Plaster Board Held Valid

Two patents, 1,029,328, covering a process for making plaster board, and 1,034,746, covering the product, the plaster board, were the subject of an infringement suit decided recently by the United States Circuit Court of Appeals, Seventh Circuit, United States Gypsum Co. vs. Bestwall Mfg. Co., 270 Fed., 542. The court affirmed the District Court's decision that the patents were infringed.

The patentee says he aimed to construct a board "the edges of which will be entirely inclosed by a sheet of covering material and in which there will be no free or exposed edges of covering material which will be liable to be torn, loosened or pulled back in the handling of the board."

It appears, therefore, that the virtue of the patent is found in the protection which the covering over the edges affords. And there was evidence to support the claim that such covering protected the exposed edge of the gypsum body, prevented waste, strengthened the finished board, increased the output, improved the appearance of the finished product and reduced the cost of production. A very large increase in the production of plaster board followed the appearance of this patented article.

Plaster boards of the two-ply and of the composite type were old and well known at the time of this discovery, says the court. The advance over the prior art consists chiefly in the protection afforded the edges of the gypsum.

The process is described by counsel as follows: "The patented method consisted, broadly, in pouring a mass

of semi-liquid flowing material upon a rapidly moving continuous sheet of paper, folding the edges of such strip upward and inward over the edges of the layer of plastic material, superimposing a narrower continuous sheet of paper upon the bottom sheet and the layer of plastic material thereon, and passing the whole between a pair of pressure rollers, whereby the layer of plastic material is compressed to a uniform thickness throughout the width of the paper where its edges are confined and bound by the inturned edges of the bottom sheet, whereby the superimposed upper sheet is secured to the layer of plastic material and to the inturned edges of the bottom sheet by the adhesiveness of said material itself."

The evidence showing the extensive use that immediately followed the appearance of the new board the court thought was sufficient to show its utility. One issue alone was presented the court: Does the contribution of the patent spell invention?

QUESTION OF INVENTION RAISED

Utility, increased output, improved product, reduction in cost, are all factors that have been thrown into the scale and are somewhat determinative of this issue, as the court saw it. But the Court of Appeals did not agree with counsel for patentee that this patent was a "broad novelty," nor with its expert witness that it was a "daring conception." And it says invention is not determined by the extent of the advance in any art which the inventor makes.

In this suit the court found that the use of a covering as a retaining member with its resulting advantages heretofore enumerated was novel. Moreover, to utilize the plastic material thus inclosed as an adhesive material, in securing the edges of the retaining member, and to attach the top cover member to it as described in the process were novel and somewhat ingenious. Such double use of the plastic material together with the retaining member permitted the manufacturer to increase its output, to lessen the cost of production, to make a more sightly board which "chipped" less readily than the board previously used, all of which under the circumstances the court held to be novelty amounting to invention.

The process patent used the term "alternate layers of plastic material," and the Bestwall company's claim of non-infringement was based in part on the assertion that its product does not contain "alternating layers of plastic material" nor are they used in its process, but the board is made in a single plastic layer.

In reply to this the Gypsum company contended that the building up of the body of the board in alternate layers of plaster and paper was not of the essence of the invention, but that the really new things discovered by Utzman were the upturning of the edges of the bottom layer of paper and then sealing or impressing the top layer of paper, a little shorter than the completed board, over the upturned ends of the bottom layer and into the layer of plaster. There is a rule of law laid down in another case (120 Fed., 260) to the effect that an element of a claim not essential to the result which the inventor desired to accomplish is not absolutely requisite in an infringing device. Therefore it was contended that since the construction in alternate layers not being essential to the result which the inventor Utzman wishes to reach, the fact that the defendant does not use alternate layers in its board is immaterial.

The Use of Inert Gas for the Prevention of Explosions

Complete Combustion of Coke in a Specially Designed Generator Gives a Mixture of Carbon Dioxide and Nitrogen Which May Be Employed Effectively for the Prevention of Explosions—Tests With Sulphur-Dust-Laden Atmospheres

BY EDWARD F. WHITE

EXPLOSIONS in industries are not always the result of failure to recognize the flammability of the materials used or the means available for the prevention of fire.

Many manufacturing operations, involving the separation and synthetic compounding of different elements, require the handling of flammable, gaseous and pulverized materials, in processes wherein it has been impossible to guard successfully against accidental fire and explosions. For this and many other reasons it cannot be asserted that a possible means for providing against explosions is available for every case. There are, however, many instances of recurrent disastrous explosions which might never have occurred if available and well-understood means for prevention had been employed.

The purpose of this discussion is to call particular attention to one such means—namely, the use of inert gas as CO_2 plus N_2 manufactured on the premises for the purpose by burning coal or coke in a suitably arranged apparatus, so that the products of combustion containing no free oxygen are collected in a holder to be drawn from as called for. This, in the writer's opinion, may in many cases be even more effectively employed for the *prevention* of fire than it has been as forming the basis of operation in the modern fire extinguishers now for many years. It is now a known fact that in many dust-making operations, including such as involve the use of dust collectors, dust flues, inclosed elevators and conveyors, pulverizing and disintegrating machines, the circulating, dust-laden atmosphere can be made inert, that is to say, deprived of free oxygen to an extent sufficient to make the existence of fire an impossibility. Reference is made to this

particular line because it is one of the most prolific fields of disastrous fires and explosions and offers the most ready and convenient opportunity for the application of the inert gas preventive. The handling and milling of grains, manufacture of food products, the grinding of sugar, starch, castor oil meal, spices, chemicals, coal, wood and other carbonaceous materials, develop dust products which ignite and propagate flame readily.

Some interesting information is here given concerning the use of inert gas in the manner above described, to prevent the explosion of sulphur dust in a milling process involving the use of all the types of machinery above referred to with result of preventing absolutely explosion of the sulphur in any parts of the operations or machinery, so long as the gas was maintained and used in the manner planned for and specified to be used.

INERT GAS GENERATOR

The gas-making plant (Figs. 1 and 2) consists of four principal parts—namely, the primary generator *A*, a secondary generator *B*, a combination gas scrubber and cooler *C* and a gas holder *D*. In operation fire with coal, or preferably coke, produces the initial gas (products of combustion) in the primary generator *A*, which is a closed furnace with controlled air supply under pressure of about 4 oz. per sq.in., furnished by an ordinary pressure fan blower. The products of combustion pass from the top of the primary generator into the secondary generator, in which they mix with a further supply of air, regulated for complete combustion, the heat of combustion of which maintains the checker work filling of the secondary generator at a dull red heat, so that the gases leaving the secondary generator consist only of completely oxidized combustion products and nitrogen. The gases now pass into the scrubber and cooler through a cold water spray and layer of broken coke, being freed thereby of any dust mechanically carried over in the gas, cooled and delivered into the holder ready for use.

A plant of the above description for the production of 3,000 to 5,000 cu.ft. per hr. of inert gas is operated with labor only for fueling say three or four times in 24 hr., the cleaning of the fire and removal of ashes, perhaps twice daily, and a sufficient general oversight while running to maintain the correct air supply and testing of the gas (which latter may be automatic and continuous) to secure uniform production.

From various records of operations in the writer's experience, the following practical observations are noted:

An ordinary disintegrating mill of capacity 1 to 3 tons per hr. will have sufficient supply of inert gas

FIG. 1. FRONT VIEW OF GAS GENERATOR

FIG. 2. SIDE VIEW OF GAS GENERATOR

through a $\frac{1}{4}$ - to $\frac{3}{4}$ -in. globe valve if the gas pressure at the valve is about 3 oz. per sq.in.

A large tight housed bucket elevator, with single leg say 50 ft. head to boot shaft, will have a sufficient supply of inert gas through a $\frac{1}{2}$ - to $\frac{3}{4}$ -in. globe valve if the pressure at the valve is about 3 oz. per sq.in.

A 500-cu.ft. floating bell gas holder will supply gas through a $\frac{3}{8}$ -in. globe valve for about 1 hr.

A standard Gas Engineering Co. 36-in. gas-generator set will fill a 500-cu.ft. bell holder in from 5 to 10 min., under normal conditions, according to openings given to combustion air valves.

Fuel consumption, if coke, with 36-in. set above referred to, operated at normal rate, will be about 50 lb. per hr.

Estimated cost of 1,000 cu.ft. gas, if coke costs \$20 per ton, about 8c.

As a matter of interest in connection with the study of explosions and means of preventing same, some helpful information is given below as obtained by the writer's investigations experimentally to determine the nature of and how to remedy explosions in the process of handling sulphur. The tests were with a special outfit set up for the purpose, as shown in Fig. 3, and described hereafter.

The questions to which answers were sought by the experiments may be stated as follows:

In a sulphur-dust-laden atmosphere, what proportion of sulphur dust in the air makes an explosive mixture?

What conditions seem especially noticeable in the propagation of fire in such atmosphere, particularly as to the extinguishing effect of the products of combustion resulting from the first burning and in the immediate vicinity of the place of ignition, the question being whether the explosion, or more specifically, the effect of a rapidly propagated fire—which an explosion is—may not be prevented by a partial elimination of the free oxygen as affecting the whole circuit by selecting effective places for injecting the gas.

What per cent in mixture of CO_2 and air will positively prevent fire regardless of fineness and per cent of sulphur present, as might be caused in any confined space from a spark caused by the striking of fire; e.g., in the disk chamber of a mill or by static or dynamic electricity.

What temperature and pressure conditions result from explosions with various mixtures of air and sulphur dust more or less confined as to circulation, as compared with theoretical calculations therefor for the known quantities of combining elements present, all as indicating the probable amount of sulphur oxidized and extent or distance reached by the fire.

The explosion chamber was a piece of 10-in. wrought-iron pipe about 4 ft. long, threaded and fitted at each

RESULTS OF EXPLOSION TESTS WITH SULPHUR-DUST-LADEN ATMOSPHERES

Test Series No.	Purpose of Test	Apparatus Conditions	Ignition	Atmosphere in Chamber	Temperature of Explosion	Pressure of Explosion	Observations	Conclusions
1	To explode measured equivalents of sulphur and oxygen.	Chamber closed, dusting by means of fan agitation.	Could not ignite.	Air			Saw good spark before closing chamber.	As repeated and sustained spark acting before and after and during running of fan failed to fire, evidently the intimacy between sulphur and oxygen was not close enough for combination, due to not enough dust of proper fineness and too slight circulation in immediate vicinity of the spark.
2	To explode mixtures of sulphur in excess of air.	Same as above except cover loosely laid on, held down by 2 bricks.	Only when S was double or more than the calculated equivalent	Air.	Varied from slightly warm to quite warm.	Never enough to show on gage but lifted cover and 2 bricks.	Inside of chamber showed fire was where sulphur was thickest and near spark plug.	Low pressure resulted probably from only partial combustion, due to the smothering effect of products of combustion of initial fire in connection with slight circulation, which prevented bringing up of fresh oxygen into the field of ignition.
3	To observe effect of excess of air and circulation.	As above except used top and bottom air valves.	Every time with positive explosion.	Air.	Decidedly warm.	Caused hissing through valves.	Noticed marks of burning S all parts of chamber especially around spark plug.	During this series of experiments it was noticed that by leaving the vent (air) valves opened, and running the fan continuously, explosions occurred at fairly uniform intervals, longer or shorter, according to the amount of air passing and the time required for purging after each explosion, showing conclusively the effect of the products of combustion to prevent firing. Very positive marks of firing were noticed in all parts of the chamber, and the explosions were decided detonations. From this the propagating effect of the oxygen-bearing air to carry the fire to all parts reached is obvious.
4	To determine what proportion of CO_2 prevents explosion.	Same as in test No. 2	With less force as gas increased.	Air and CO_2	As before under like conditions.	As before under like conditions.	Checked gas per cent in chamber by laboratory test of sample.	20 to 25 per cent of CO_2 in air, at normal atmospheric temperature and humidity, will undoubtedly prevent explosion of sulphur dust by spark ignition from any cause or source. By CO_2 is understood ordinary commercial carbonic acid made by the elimination of free oxygen from air through a process of burning coal or coke. Such gas, of course, contains a large percentage of nitrogen.

NOTE.—The sulphur used in these experiments was crude brimstone, ground, dust-chamber separated, and bolted through silk about 120 mesh. A sample of the crude before grinding showed less than 0.8 per cent moisture. A good per cent was impalpably fine. The experiments were made out of doors, on the afternoons of two different days in September, 1920. The weather was clear, temperature about 70 deg. F. Humidity about 85 per cent of saturation.

end with a standard 10-in. pipe cap. An 8-in. disk fan was placed axially with, and near the bottom of, the chamber, on a shaft journaled through the bottom cap and fitted on the outside end with a pulley for driving by an electric motor. This fan acted as an agitator for the sulphur and served also to excite a circulation of the atmosphere inside the chamber. The top cap was removable by unscrewing and during the trials was replaced by an asbestos-paper-lined light wooden cover laid on and held down with two common red bricks. Both top and bottom covers were fitted with 1-in. globe valves for the passing of the atmosphere into or out of the chamber. The ignition was by means of an ordinary series group of dry batteries (about 8) and an ordinary spark plug, the latter being placed in the side of the chamber about midway between top and bottom; also in the side of the chamber

FIG. 3. APPARATUS FOR EXPLOSION TESTS WITH SULPHUR DUST

opposite the spark plug was a pressure gage, near which was an opening fitted with a valve for admitting inert gas. The inert gas used was CO_2 , taken from a gas cylinder through a water displacement gasometer. The sulphur for dusting was dropped into the chamber by removing the top cover while the fan was not running.

Some variations of conditions were made during the trials, most important of which were as follows:

Sparkling was done both with fan running and not running; that is to say, immediately following the stop and start of the fan;

The chamber was placed alternately in vertical and horizontal positions;

Several trials were made with each change and also charge of sulphur, preceded in every case by removal of cover and purging of chamber, by doing which it was possible with marked accuracy to obtain repeatedly very similar effects, depending upon the conditions set;

The activity of circulation within the chamber was varied under control by means of the air globe valves at top and bottom of the chamber.

As only approximations to actual conditions were possible to observe, the conclusions are correspondingly of indicating or empirical value, but it is the writer's belief that significant inferences may be drawn by study of the accompanying tabulation of the results of the tests.

A Plan to Reduce the Time and Cost of Air-Seasoning Wood

In co-operation with the sawmills and wood-utilization plants throughout the country, the Forest Products Laboratory, Madison, Wis., is organizing an extensive field study on the air-seasoning of wood. This study, it is believed, will be of extreme interest to the lumber manufacturer and to the wood-using industries. The purpose is to determine the piling practice which will result in the fastest drying rates consistent with the least depreciation of stock, the least amount of required yard space and the lowest handling costs. The study will be carried on concurrently on both hard woods and soft woods.

The air-seasoning of wood is an old practice. No systematic attempt has ever been made, however, to work out the exact conditions under which drying time and drying costs can be reduced to a minimum. It is not actually known which of the numberless methods of piling will give the quickest and the cheapest results under given climatic conditions. The new project will furnish a comparison of the effects of such piling variables as sticker heights, the spacings of boards in layers, the heights of pile foundations and the directions of piling with relation to prevailing winds and yard alleyways.

The study is expected to decide whether from a business standpoint lumber should be dried partly at the mill and partly at the plant of utilization, or whether it should be completely dried at the mill. The data collected will also go a long way toward showing whether air-seasoning or kiln-drying is the more profitable.

A tentative working plan of the air-seasoning study has been prepared by the Forest Products Laboratory, and copies are being sent to the secretaries of the various lumber and wood-using associations, state foresters, forest school heads and others.

Co-operation in the air-seasoning study is being offered on every side. As yet the plants at which the work will actually be done have not been definitely chosen, but the extreme interest already manifested indicates that there will be no difficulty in securing co-operation with plants ideal for the study. Actual field work will soon be well under way.

Estimated Production of Iron and Steel in Japan

The recent report of the financial and economic committee appointed by the Japanese government to study the future development of the mineral production of the country, as published in the *Far Eastern Review*, gives the following forecast of the production of iron and steel for the five years mentioned and of the coal and iron ore required under peace conditions:

Years	Production		Requirements	
	Pig Iron Tons	Steel Tons	Coal Tons	Iron Ore Tons
1920	377,616	1,031,350	6,040,000	3,709,000
1921	468,000	1,099,000	6,473,000	3,978,000
1922	437,000	1,164,000	6,926,000	4,275,000
1923	466,000	1,227,000	7,339,000	4,517,000
1924	492,000	1,287,000	7,733,000	4,786,000

The committee considers that the best policy to follow is the grouping of the various works and the levying of protective tariffs ranging from 10 per cent *ad valorem* on iron ore to 15 per cent for steel, material for ship construction remaining free as at present. The builders using native steel would receive a subsidy equivalent to the import duty.

Casting Aluminum:Zinc Alloys

BY F. A. LIVERMORE

ALUMINUM, as a material for casting, presents many advantages as regards lightness, good machining properties, a fair amount of strength and freedom from brittleness, the widespread adoption of aluminum alloy castings of recent years sufficiently demonstrating their reliability to withstand severe service.

It is a well-known fact that pure aluminum is entirely too soft to produce satisfactory castings which will be subject to any strain, owing to its comparative softness and lack of strength. To overcome this it is the universal practice to stiffen the metal with some hardening element, the amount and nature of the hardening element or elements depending on the physical and mechanical properties required.

Practically all the standard aluminum alloys used in the foundry can be successfully cast, but there are two main classes of aluminum casting alloys:

(a) Those whose principal hardening medium is zinc (with or without small percentages of other elements).

(b) Those containing copper as the hardening constituent.

We find class *a* extensively used in British aluminum foundries, while the copper alloy is favored by the French and American foundries.

Aluminum:zinc alloys have the reputation of being particularly subject to fatigue failures; this is due to the weakening effect of certain impurities of commercial spelter. Lead in particular is very deleterious to any aluminum alloy, and when castings of the zinc base alloy are required to pass severe physical tests, only high-grade zinc should be used. Other dangerous impurities are carbon, silicon and iron, hence the greatest precaution should be taken to prevent the introduction of this foreign matter either in the metal used or through the medium of crucibles and tools.

PRECAUTIONS TO BE TAKEN IN MELTING ALUMINUM ALLOYS

In melting aluminum alloys, plumbago or salamander crucibles (preferably with clay liners) should be used.

Melting is best carried out in a gas-fired furnace using a mixture of air and gas which can be adjusted to prevent overheating and subsequent burning of the metal. Electric furnaces are claimed by their proponents to be when properly made much more reliable and cheaper than the gas furnace or any other type of furnace. No charcoal or carbonaceous covering is used on the metal, as carbon combines with the alloy, forming a very brittle compound. Gates and sprues from castings must be freed from sand as nearly all the sand introduced into the pot is reduced to silicon, which weakens the alloy. In cases where there is a great danger of introducing sand, it is found beneficial to add powdered flux (75 per cent of potassium chloride and 25 per cent fluorspar). This tends to dissolve the silica and so keep it from combining with the aluminum.

It is found that a tough film of oxide often surrounds borings, turnings, chips and other scrap aluminum, making it extremely difficult for melting. This oxide can be dissolved off by heating with the alkali earths. The following process is recommended by the British Aluminum Co., Ltd.: The chips or other fine scraps are intimately mixed with varying amounts of flux (85 per cent of common salt and 15 per cent powdered fluor-

spar) depending upon the degree of cleanliness, and the whole is melted at a fairly high temperature.

Special precaution should be exercised when melting to prevent overheating, as this appreciably effects and is injurious to the working properties of the casting. The pouring temperature has a very noticeable effect upon the resultant castings. In general, the temperature should be as near the melting point as possible. After a considerable amount of research I have found by adhering to this rule an increase of 8,000 lb. per sq.in. in tensile strength is obtained together with a marked improvement of the surface appearance of the casting. The temperature I recommend is 650 deg. C. $\pm$ 10 deg. C.

In quite a number of British foundries the archaic method of guessing the temperature by the eye is still in vogue, and I am confident that a large percentage of the unsound work produced is due to this, what I think we can call discrepancy or oversight. All aluminum castings should be under strict pyrometric control to obtain satisfactory results, and I may add that the outlay for the installation is quickly compensated by a corresponding increase in sound production.

Just before pouring, a little flux is added to the molten mass and the metal is thoroughly stirred with a clay-covered skimmer. Flux tends to reduce the oxides and dross in the metal and put it in ideal condition for pouring; otherwise the heavy oxide which is occluded throughout the metal would cause blow-holes. The dross which forms on the surface must be removed with special care; the skimming should be done with a degree of thoroughness, as a little dross is likely to remain under the surface and pass into the casting.

An aluminum casting has a characteristic cleanliness when removed from the mold and very little dressing is required. In grinding off any rough spots, workmen often find that the emery wheel has a tendency to gather particles which interfere with the grinding; I find that a little lard-oil or grease on the surface of the emery wheel will prevent this clogging and thus insure smooth cutting with maximum efficiency.

The difficulty of welding aluminum has been overcome by treating the surface to be welded with a mixture of alkaline chlorides and fluorides, which completely dissolves the film of oxides formed. In one method, a mixture of four parts of potassium chloride, three parts sodium chloride and one part of sodium fluoride with a melting point of about 660 deg. C. gives very satisfactory results.

Cracks, shrink-holes, pinholes or other defects can be filled by means of an oxy-acetylene blowpipe.

In connection with the work I have carried out on alloys of aluminum, I have found the laboratory an indispensable asset; the co-operation on the part of the chemist has elucidated difficulties which may otherwise have been left unsolved.

Notes on Oil Shale Industry

The Bureau of Mines has recently issued some notes on the oil shale industry which are preliminary to the publication of a general bulletin on this subject. The history of the industry and its status in Scotland and the United States are discussed, and the method of assaying oil shales used in the Bureau is compared with the procedure used by the largest of the Scottish producers. A selected bibliography of approximately a hundred references is appended.

Briquetting Mineral Phosphates

Reducing Conditions Being Essential in the Production of Phosphoric Acid by the Volatilization Process, the Authors Have Investigated the Briquetting of Mixtures of Florida and Tennessee Phosphates With a Reducing Agent (Coke, Coal, Peat)

BY WILLIAM H. WAGGAMAN, H. W. EASTERWOOD AND T. B. TURLEY

Bureau of Soils, Washington, D. C.

THE briquetting of metals or minerals for industrial use is practiced as a rule for one of two reasons: first, either to utilize natural deposits of finely divided minerals which must be in nodular or lump form in order to handle them with commercial success, or second, to eliminate the loss or waste resulting from other mining or manufacturing processes where large tonnages of ore fragments and metallic filings and trimmings are produced. In countries therefore where natural deposits of high-grade coal and metallic ores have become less plentiful the science of briquetting and the perfection of briquetting machinery have made their greatest advances. As an example of this the general type of machine so successfully employed in making fuel briquets was long known as the Belgian roll press, because it originated in Belgium.

While briquetting has been practiced in certain European countries for many years, it is a comparatively new development in the United States, largely because our natural resources have been so great that we have felt little need to economize or to utilize fully our industrial wastes. Up to the present most of our effort has been spent upon the briquetting of the dust and culm incidentally obtained in the mining and preparation of anthracite coal, and so successful has the briquetting of coal proved that, according to the figures of the U. S. Geological Survey,¹ our output in 1918 amounted to 477,235 net tons. With the gradual exhaustion of the cream of our better grades of ore, however, and an ever-growing tendency toward greater efficiency in industry, briquetting processes promise to occupy a much wider field.

According to Stillman² investigations have been made and considerable success has been attained in the briquetting of a great variety of materials, such as carbonized lignite, hard steel, copper and tin ores, hardwood, metal leaf, and paper, sawdust and copper, steel and brass trimmings.

Recent advances on a new process of producing phosphoric acid from mineral phosphates has made the briquetting of phosphate rock a matter of considerable interest, and it was with a view to determining how widely applicable this method might prove to our more important phosphate deposits that the work described herein was undertaken.

THE DEVELOPED PHOSPHATES OF THE UNITED STATES

While the United States possesses larger known deposits of phosphate rock than any other nation in the world, our supplies at present are drawn from two main phosphate fields—namely, those of Florida and Ten-

nessee. The deposits in our Western States (Utah, Idaho, Wyoming and Montana), though vastly greater than those in the East, are so far removed from the fertilizer market that they are being exploited at present to only a limited extent. In both Florida and Tennessee a considerable quantity of the higher grade rock has already been mined, and though these fields are by no means exhausted, very elaborate and costly mining methods must now be employed in order to obtain the grade of phosphate rock which the fertilizer operator demands for the manufacture of acid phosphate. Modern methods of preparing phosphate for the market involve washing and screening the rock, which entail a considerable loss of finely divided phosphate due to its discharge upon the dumps along with the impurities carried in the deposits.³ The impurities thus removed are mainly silica and the oxides and phosphates of iron and aluminum, the first-mentioned being objectionable because of its diluting effect and the two latter chiefly because of the undesirable chemical and physical properties which they impart to the product.

THE VOLATILIZATION PROCESS OF OBTAINING PHOSPHORIC ACID

The process which has been receiving considerable attention within recent years is that based upon the volatilization of phosphoric acid from mixtures of phosphate rock, sand and coke by heating such mixtures to smelting temperature. Since the presence of silica or silicates is essential to bring about the chemical reactions involved, it is not necessary to employ high-grade phosphate rock for this process—in fact, if the furnace plant is located at the phosphate mines, it would be a foolish practice to eliminate the silica present in the deposit by a costly washing and screening process only to put this material back in order to obtain the proper lime and silica ratio required in the furnace charge. Moreover, the presence of a relatively high percentage of aluminum oxide or phosphate or both is apparently an actual help to the successful working of the process, since these compounds tend to lower the melting point of the slag obtained and thus facilitate the escape of the phosphoric acid.⁴ While the oxides or phosphates of iron are usually reduced to an iron-phosphorus alloy (ferrophosphorus), there is a ready market for this latter product and therefore the presence of iron in the phosphate deposit does not entail the loss of the amount of phosphorus equivalent to this metal.

Until the past year it was generally believed that the production of phosphoric acid by the volatilization process could be successfully and completely accom-

³Waggaman and Wagner, *J. Ind. Eng. Chem.*, vol. 10 (1918), p. 353.

⁴Waggaman and Turley, *J. Ind. Eng. Chem.*, vol. 12 (1920), p. 646.

plished only in the electric furnace. Since phosphoric acid for fertilizer purposes must always be a relatively cheap product, it appeared doubtful if this process would have a very wide application in this country, because of the scarcity of cheap electric power. For this reason the Bureau of Soils in its laboratories for technical research undertook an investigation to determine if it were not possible to employ fuel for smelting mixtures of phosphate rock, sand and coke in lieu of the electric arc. This work has reached a status where it holds forth considerable promise of economic success,⁵ but the data so far obtained indicate that the successful briquetting of mine-run phosphates is a factor of very great importance to the commercial practicability of the process in Florida and Tennessee.

Experiments have shown that in order to obtain complete volatilization of the phosphoric acid from such mixtures it is highly important if not essential that reducing conditions be maintained within the mass of reacting materials until the charge is brought to a state of incipient fusion. These conditions are not difficult to maintain in the electric furnace, where the heat required in the smelting operation is not dependent upon oxidation, but where fuel is used as a heating source, air or oxygen must be introduced into the furnace in order to obtain the heat units necessary to attain a smelting temperature. If reducing conditions are maintained in such a furnace by the incomplete combustion of the fuel, not only is it difficult to obtain the temperature desired but in furnaces of the ordinary type a great loss or waste of combustible material results.

REALIZATION OF REDUCING CONDITIONS BY BRIQUETTING A MIXTURE OF PHOSPHATES AND COAL

After a considerable amount of experimentation it was decided that the most feasible method of bringing about the desired reactions in such mixtures as outlined above was to employ fuel from an outside source for the heating of the charge but to mix coke or some other carbonaceous material intimately with the phosphate rock and sand to act as the reducing agent. Even under these conditions, however, considerable difficulty was experienced in preventing this reducing agent from burning out of the charge and thus bringing the reaction to a standstill.

The most efficient form of furnace yet employed in trying out this method has been of a type combining the features of both the open hearth and blast furnaces in which the gases of combustion ascend through the green charge preheating it to the necessary temperature before it is fed upon the hearth. Since the mine-run phosphates of Florida and Tennessee could not be treated in their natural state in such a furnace because of the difficulty of forcing the phosphoric acid evolved and gases of combustion through a column of finely divided material, it soon became apparent that such material must be either nodulized or briquetted to allow a free passage for the gases between the interstices of the green charge. It was also found that by intimately mixing finely ground coke or other carbonaceous material with the sand and mineral phosphates and pressing or molding the mass into lumps the bulk of the reducing agent could be protected against oxidation and thus held available to bring about the necessary chemical reactions in the furnace. Because of the nature of the Florida

phosphates and certain advantages which fuel offered as a heating agent over the electric arc, briquetting appeared to be more feasible than nodulizing. According to investigations were undertaken to determine the most economic methods of making briquets from mixtures of phosphate rock, sand and coke for subsequent furnace treatment.

BINDING MATERIAL A PRIME FACTOR IN THE BRIQUETTING OF MINERALS

Investigations so far conducted on the briquetting of coal and lignite⁶ seem to show that the nature, quantity and value of the binder employed are the factors of prime consideration. The requirements which such a binder must fulfill are as follows: First, it must produce a briquet capable of withstanding the shocks incident to heavy handling and shipping; second, it should be practically waterproof, so the briquets will not disintegrate on exposure to wet weather; third, it must maintain its binding qualities on heating so that the briquet will not fall to pieces in the fire; fourth, it should add to rather than detract from the fuel value of the briquet; fifth, it must be sufficiently cheap to warrant the marketing of the briquets in competition with other fuels.

The problem of briquetting mineral phosphates is by no means analogous to that of briquetting coal, because even after the phosphate is briquetted it is still in the nature of a raw material which must be treated at its source of supply before it can be converted into a marketable product. If the furnace process of producing phosphoric acid is to be employed in treating the run-of-mine phosphates of Florida and Tennessee, it is logical that the plant be located at or near the phosphate deposits. The handling of the briquetted charge, therefore, would be reduced to a minimum and there is little reason for making the briquets waterproof, since they would not have to be shipped or stored in the open. Moreover, inorganic binders which are considered so objectionable in making fuel briquets because of the extra ash which they add are permissible in the case of briquetting mineral phosphates provided they do not interfere with the chemical reactions involved in the furnace process. Finally, the fact that the use of briquets made from mine-run phosphates offers a promising means of eliminating what at present constitutes an enormous loss or waste of a valuable fertilizer asset and therefore the actual cost of briquetting might well exceed that of preparing high-grade phosphate rock for the market and still prove economical makes the problem distinctly different from that of briquetting coal, lignite or other fuel.

EXPERIMENTAL WORK ON BRIQUETTING FLORIDA PHOSPHATES

The first experimental work was conducted with Florida phosphates from both the hard rock and land pebble fields, using a small hand press capable of making only a single briquet at a time under a pressure of a ton to the square inch. Various organic and inorganic binders were tried on mixtures of sand, coke and high-grade (washed) phosphate rock from these sources, but none of them proved very satisfactory either on account of their weak binding action or because of their prohibitive cost. It was found, however, that the clay-like material which occurs in many of the deposits inti-

⁵Waggaman and Turley, *CHEM. & MET. ENG.*, vol. 23, p. 1057 (1920).

⁶Wright, C. L., *Bull.* 58, Bureau of Mines.

mately mixed with the phosphate rock acted as a very efficient binder when from 8 to 12 per cent of water was present in the final mix. Briquets were thus produced from run-of-mine phosphates (containing only natural binder) which proved so satisfactory in resisting severe shatter tests and in retaining their form unaltered during the preliminary heating in the furnace that large batches of material were made up and briquetted in roll presses of commercial size through the courtesy of the Lehigh Coal & Navigation Co., of Lanford, Pa., and the General Briquetting Co., of New York City. Briquets have thus been turned out in lots of several tons which were subsequently successfully treated in an oil-burning furnace at Arlington Farm, Va.⁷

DESCRIPTION OF THE PRESS USED

A number of mechanical and chemical problems arose, however, in connection with briquetting mineral phosphates and their subsequent use which it was deemed desirable to work upon, but in order to prepare the briquets for experimental purpose it was necessary to build a small briquetting machine which could also be depended upon to make up charges sufficiently large for treatment in a furnace of semi-commercial size. Ac-

FIG. 1. BRIQUETTING MACHINE USED IN MAKING UP PHOSPHATIC CHARGES FOR FURNACE TREATMENT

Briquets of Florida phosphates on left and of Tennessee phosphates on right.

cordingly the machine shown in Fig. 1 was built from an old cider press and may be briefly described as follows:

Four vertical steel plungers $2\frac{3}{4}$ in. in diameter are rigidly bolted to the upper part of the steel framework of the machine. These plungers are directly above two horizontal steel plates fitted one above the other and

having four perforations in each corresponding in size to the plungers. The upper plate is held rigid and into its perforations are fitted four brass cylinders 3 in. in length which hold the mixture to be briquetted. By means of a lever the lower plate may be revolved so that the perforations therein will correspond to those in the upper plate and thus furnish a free passage for the plungers through each cylinder, or it may be so turned so as to close the bottom of the cylinders, forming a base upon which the briquets are pressed.

Both plates are mounted 3 in. above the bed plate of the press, which rests in turn upon the head of a 4-in. steel piston operating in a rigid sleeve. The necessary pressure is furnished by a small hydraulic pump operated by a 2-hp. motor.

To operate the press the piston is lowered by opening the valve controlling the water supply and permitting the water to flow back into its reservoir. The lower one of the two horizontal plates is then turned so as to form a base for the brass cylinders fitted into the perforations of the upper plate, and into these cylinders is loosely packed the mixture to be briquetted. The hydraulic pump is now started and raises the piston head carrying the brass cylinders filled with phosphate charge, pilot rods guiding these cups so that the four plungers are forced into them, pressing the mixture into briquets. When the pressure reaches 2,500 lb. to the square inch the valve controlling the pump is momentarily released, the lower plate revolved so as to open the bottom of the cylinders, the pressure again applied and the briquets forced out. In actual operation eight brass cylinders are provided, so that while four briquets are being made the supplementary cylinders are being filled.

MECHANICAL AND CHEMICAL PROBLEMS INVOLVED IN BRIQUETTING MINERAL PHOSPHATES

The mechanical and chemical problems involved in the briquetting and use of mineral phosphates may be conveniently grouped as follows: (1) The mechanical composition of the material which best adapts it for briquetting purposes. (2) The chemical composition and its control. (3) The degree of fineness to which the mixture must be reduced to produce satisfactory briquets. (4) Methods of incorporating into the mixture the water necessary for imparting to the natural binder its cementing qualities. (5) The best proportion of water to use for this purpose. (6) The effect of reducing agents upon the briquets.

A number of experiments conducted with samples of mine-run phosphates from the Florida fields showed that satisfactory briquets could be made from mixtures of phosphate rock, sand and coke if the percentage of material classed as clay (according to the system of mechanical analysis employed in the Bureau of Soils⁸) was equal to or exceeded 20 per cent of the entire mass.

EXPERIMENTAL WORK IN BRIQUETTING TENNESSEE PHOSPHATES

It seemed desirable to ascertain if the briquetting process which proved successful with Florida phosphates could also be applied to the Tennessee phosphates, particularly to those deposits which require elaborate plants to prepare a product suitable for the fertilizer industry. Moreover, many of the deposits in the brown rock phosphate fields of Tennessee from

* Mechanical analyses made according to the conventional method employed in classifying soil types in the Bureau of Soils.

which the high-grade lump rock has been removed are now being reworked and much valuable material recovered. There are also immense beds of disintegrated phosphate rock in the southern part of this state which are frequently so high in silica that it is uneconomical to mine them. The senior author made a trip to these fields early in the year to examine the nature of many of these deposits and to determine if it were possible to briquet the mine-run phosphates and utilize them in the furnace process. Average samples of from 200 to 250 lb. each were taken from the various deposits and both mechanical and chemical analyses were made. Most of the experiments described below were conducted with samples from the Tennessee fields.

In Table I is given the mechanical analysis of the phosphates on which briquetting experiments were conducted.

Inspection of Table I will show that as far as their mechanical composition is concerned all of the samples of phosphate, with the exception of Nos. 1-T, 6-T, 8-T and 17-T, contained sufficient material classified as clay to bind them into satisfactory briquets. But the ultimate mechanical composition of the mix depends also upon the amount of sand or rock which must be added

to obtain the proper silica lime ratio in the furnace charge, therefore the fitness of these mine-run phosphates for briquetting purposes and subsequent furnace treatment must be determined by their chemical composition.

In Table II are given the chemical analyses of the same samples, together with the ratio of lime to silica therein. The quantities of sand or high-grade rock which must be added to 100 parts of the sample in order to obtain the proper relation between lime and silica to

* The fixed carbon plus ash considered as coke. The coke used in these experiments contains 14.9% of ash. An analysis of this ash showed that the coke in the briquetted mixture adds 0.98% SiO₂, 0.02% CaO, and 0.63% Al₂O₃, Fe₂O₃, to the mix.

bring about the reaction involved in the volatilization process are also shown in this table.

The phosphoric acid content of Nos. 8-T, 9-T, 10-T, 12-T, 13-T and 16-T are so low as to eliminate these samples as commercial possibilities unless they are reinforced with a considerably higher grade phosphate rock. Most of the samples low in phosphoric acid, however, were taken from the waste ponds of old phosphate plants and represent the detritus washed out from run-of-mine material in preparing a high-grade rock for the market. It will also be noticed that in almost every instance these lower grade phosphates contain a high proportion of both the clay-like binding material and silica and hence offer a promising source of material to mix with higher grade phosphates low in these two ingredients.

In Table III are given the quantities of sand, coke and better grades of mine-run phosphate used in making up the briquetted charge. The composition of the briquetted mixture (air dried), is also given in the same table.

In the cases of Nos. 14-T and 18-T the percentage of

phosphoric acid in the briquetted charge was somewhat lower than in the other mixtures. This is no doubt due to the fact that in addition to the lime combined with phosphoric acid a part of this base present in the original phosphate samples was in the form of carbonate and therefore the sand added to take care of the lime in this latter compound reduced the percentage of phosphoric acid in the briquets.

In Table IV the same data are given for mixtures of two or more samples of phosphate and the figures show how deposits of low-grade phosphate may be utilized by

* The fixed carbon plus ash considered as coke. The coke used in these experiments contains 14.9 per cent of ash. An analysis of this ash showed that the coke in the briquetted mixture adds 0.98 per cent SiO₂, 0.02 per cent CaO and 0.63 per cent Al₂O₃, Fe₂O₃ to the mix.

mixing the material with that from adjacent or nearby deposits of higher grade.

In preparing the materials for briquetting purposes they were first dried down to a point where they contained approximately from 2 to 4 per cent of moisture. They were then ground in a small grist mill and passed through a sieve having fifteen meshes to the linear inch. Although some preliminary experiments indicated that finer grinding imparted somewhat greater resisting power to the briquets, the difference between the durability of the briquets produced from the materials of these different degrees of fineness was not sufficiently great to warrant the additional expense involved.

One of the problems encountered in preparing the ground material for briquetting purposes is to find a satisfactory method of introducing the necessary water to give the mass its binding qualities. At least 10 per cent of water must be contained in the mixture before satisfactory briquets can be produced, and if this water is merely poured or sprinkled upon the material the clay contained therein has a tendency to ball up and prevent

the uniform distribution of the moisture. Introducing the water, however, by means of sprays or atomizers while constantly turning the mass gave a very uniform distribution and prevented the formation of clay balls. It was also found that if a basin-like depression were made in the pile of the charge to be briquetted and the necessary water poured into this basin and covered with dry material, at the end of eighteen or twenty hours the mass was in a fairly friable condition which admitted of thorough mixing.

The most satisfactory method of introducing the necessary moisture, however, particularly where the phosphate requires the addition of both sand and coke, is to mix the water with this sand and coke and then add these two ingredients to the phosphate mineral. This procedure seems to eliminate the difficulty encountered in the balling up of the clay contained in the mass.

In Table V the results obtained on briquetted charges of relatively high-grade phosphate, sand and coke are given. These briquets were made up with varying percentages of moisture and the shatter and compression tests were applied not only to the fresh briquets but to the air-dried and oven-dried samples as well.

With the exception of Nos. 3-T, 7-T and 1-F all of the briquets in the air-dried condition withstood a drop on a cement floor of from 6 to 8 ft. and a drop of 20 ft. or more upon a mass of other briquets. The drying of the briquets in an oven increased considerably the effec-

* Average weight = 109.0 g. Average H₂O content = 2.95%

tiveness of the binder, but in actual commercial practices it would scarcely be economically feasible to dry the briquets in this way. In furnace practice, however, the briquets would never be subjected to a drop of over 15 ft. upon a mass of similar briquets, and therefore for practical purposes they would meet all requirements.

In Table VI the same tests are given on briquets made up of two or more samples of phosphate rock, and it will be noted that these briquets were even more satisfactory than those given in Table V. The figures given in these tables seem to show that the moisture content required for the successful briquetting of the mixtures employed range from 8½ to 14 per cent, but on the whole briquets of a very satisfactory nature can be obtained where the average moisture content is between 10 and 12 per cent.

In order to determine the effect of high heat upon the briquetted samples a number of freshly made briquets with their full percentage of moisture were placed in a muffle furnace heated to bright redness (1,000 deg. C.). These briquets showed no signs of splitting or disinte-

grating when submitted to this severe test, but shatter tests subsequently conducted with them indicated that the internal stress set up by the rapid elimination of moisture weakened them to a slight extent. In no instance, however, was this weakness sufficiently pronounced to render them unfit for furnace use.

BITUMINOUS COAL AND PEAT AS REDUCING AGENTS

Because of the difficulty of grinding coke, its abrasive action on milling machinery and the difficulty of obtaining an adequate supply at a low price in those phosphate fields far removed from the coke ovens or municipal gas plants, a number of experiments were made to determine if bituminous coal or peat might be employed as the reducing agent in the briquetted charge.⁹ It was feared that the high percentage of volatile matter in these materials would cause the briquets to split open at the temperatures attained in the furnace, particularly if sufficient amounts were added to give the same quantity of fixed carbon supplied by the coke. Moreover, it seemed likely that in order to burn completely the extra amount of combustible gas evolved from such briquets in actual furnace practice so much air must be drawn into the system that the efficiency of the towers for collecting or absorbing the phosphoric acid would be considerably reduced.

The briquets made up with these two reducing agents stood up very well under the shatter test employed, though those containing peat were rather light and somewhat weaker than the coal and coke briquets.

By referring to Table VII it will be noted that where bituminous coal was employed as a reducing agent the amount used in making up the briquets supplied only

TABLE VII. APPROXIMATE ANALYSIS OF COKE, BITUMINOUS COAL AND PEAT, QUANTITIES USED IN BRIQUETTED CHARGE AND AMOUNT OF FIXED CARBON CONTAINED IN BRIQUETS BEFORE AND AFTER HEATING

Material	Approximate Analyses, Per Cent				Amount Added to Briquetted Charge, Per Cent	Amount of Fixed Carbon in Briquets	
	Moisture	Volatile Matter	Fixed Carbon	Ash		Dried Briquet, Per Cent	Heated to 1,000 Deg. C., Per Cent
Coke.....	0.38	0.84	84.59	14.19	12.00	10.40	9.61
Bituminous Coal	4.15	35.72	48.15	11.99	18.50	9.16	11.73
Peat.....	10.97	52.93	30.30	5.80	19.37	6.10	4.83

88.0 per cent as much fixed carbon as was furnished by the coke and where peat was used it was added in quantities supplying only 58.7 per cent as much fixed carbon as was furnished by the coke.

The coal and peat briquets made up in this manner when ignited in a muffle furnace at 1,000 deg. C. soon burst into flame, but did not split open or disintegrate as expected, although the latter briquets subsequently showed considerable porosity. The same thing held true when the briquets were placed in a forge fire, except in the latter case a glaze or slag formed over their surfaces, protecting more efficiently the carbon in the interior from oxidation.

Upon breaking open the briquets subjected to this treatment, the carbon content of those made up with bituminous coal was found so uniformly distributed throughout the mass and apparently in so much larger quantities than in the coke briquets submitted to the same treatment that it seemed probable that some of

FIG. 2. SAMPLES OF BRIQUETS (AFTER HEATING IN MUFFLE AND FORGE FIRE) MADE FROM TENNESSEE MINE-RUN PHOSPHATES MIXED WITH VARIOUS REDUCING AGENTS

Note the distribution of carbon in those made up with coal and peat (two piles to right) as compared with those in which coke was used (pile to left of center).

the volatile hydrocarbons had decomposed within the briquets and deposited their carbon content. The difference in the appearance of the briquets made up with coke, coal and peat is shown in Fig. 2.

Analyses of the ignited briquets bore out this assumption, since the actual fixed carbon found in those made up with coal was higher after ignition than before and surpassed the fixed carbon content of the briquets made up with coke. The approximate analyses of the reducing agents used, the quantities added and the fixed carbon content of the briquets before and after ignition are given in Table VII.

The fixed carbon content of the ignited coal briquets shows that over 35 per cent of the volatile matter was retained within the mass as precipitated carbon, but those briquets in which peat was used actually showed a loss of fixed carbon due probably to the fibrous nature of the peat and the consequent porosity of the briquets in which this reducing agent was used.

The deposition of carbon through the mass of finely divided minerals in the coal briquets should insure quicker and more complete reactions between the ingredients in the furnace charge and make it possible to reduce the percentage of coal used at least 18 per cent below that which was first deemed necessary.

While the results obtained with peat as a reducing agent were not as promising as those obtained when coal was employed, the indications are that the former may be used to replace at least part of the coke or coal required. It is realized that the final proof of the effectiveness of these materials in lieu of coke and the practicability of using them in the volatilization process of producing phosphoric acid must rest in the actual furnace tests which are now being planned; nevertheless the results obtained with coal are very encouraging and give promise of further reducing the cost of preparing the phosphatic charge for subsequent furnace treatment.

Chinese Vegetable-Tallow Industry

Exports of vegetable tallow from China total annually about 200,000 piculs (1 picul = 133½ lb.), most of which, before the war, was sent to the Netherlands, France and Germany. Now, however, the United States, Italy and Great Britain have become the chief buyers. The following figures quoted from the Chinese Maritime Customs show the exports of the commodity in China's trade from 1914 to 1920, in piculs: 1914, 190,094; 1915, 181,482; 1916, 256,960; 1917, 151,385; 1918, 162,881; 1919, 164,544; 1920, 69,118.

⁹Peat is available in large quantities close to the Florida phosphate fields, and bituminous coal from Kentucky is the chief fuel used by the Tennessee phosphate operators.

Eliminating Blow-Holes in Thermit Welds

A NEW grade of molding material for Thermit welding has recently been developed by the Metal & Thermit Corporation, New York, which, as proved, will definitely prevent blow-holes and assure sound welds.

The design of the new molding material, designated as "Thermit Molding Material," is based on the theory that good silica sand will stand the heat of the Thermit reaction very well and that the weakness in all molding material is the clay binder. Therefore there should be as little clay as possible in the mixture, in order to make the mold more refractory and to increase its porosity. Plastic clay has been selected instead of a fireclay. The sand and plastic clay are ground together in a foundry pan or moller, with the intention of coating each grain of sand with a minimum thickness of clay. This gives a good, clean molding material, which should be rammed hard in the mold, which will stand up well under the pre-heating flame and which is extremely porous to the gases generated in the mold, resulting in a sound weld with a very clean exterior.

THE MIXTURE USED

The mixture now being used is composed of the following: Three parts clean, sharp silica sand (100 per cent of which should pass through a screen having a 0.03-in. square opening, and 40 per cent of which should be retained on a screen having a 0.012-in. square opening), mixed with 1 part Welsh Mountain plastic clay. These parts are first thoroughly mixed in the moller together with one-fortieth part glutrin by volume and sufficient water (one-twelfth part) to bring to the proper consistency. If mixed by hand, the sand and clay must be dried before mixing (being careful not to subject the clay to a temperature higher than 400 deg. F.) and thoroughly mixed before adding the glutrin and water. The glutrin should be mixed with the water before adding to the sand and clay.

In case a plastic clay fatter than the Welsh Mountain be used, the mixing, of course, will have to be more thorough and less clay used. Welsh Mountain clay is being used in the present mixture because in carefully run tests it has proved to be the most refractory. The use of the new molding material necessitates harder packing next to the weld; in fact, the regular Thermit rammer may be supplemented by the use, for instance, of a tool having an end $\frac{3}{8} \times 1\frac{1}{2}$ in., so that the operator may be able topeen the sand next to the wax collar and the various patterns.

PRECAUTIONS THAT ARE ESSENTIAL

It is absolutely essential, in the production of sound welds, to be sure that no loose sand exists in the mold when the Thermit steel is poured. This is why very hard ramming is advocated, also why it is most important to blow out all loose material from the interior of the mold by putting the pre-heating burner in the riser before the heating gate is plugged and being sure that no sand is detached by the operation of inserting this heating gate. The burner should be removed from the riser before plugging the heating gate, because otherwise it may detach some sand, which could not be blown out after the plug is in place. The heating gate plug should be thoroughly dry, and if it has been car-

ried in stock for some time, it should be warmed before using.

By perforating the sides and bottom of the mold box, the escape of the gases which pass through the molding material is greatly facilitated; $\frac{3}{4}$ -in. diameter holes, spread 3 or 4 in. apart, are sufficient. To facilitate the escape of gas from the bottom of the mold box, the mold should rest on blocks, not directly upon the foundry floor.

As unnecessary molding material simply increases the resistance to the passage of gas, the mold box should be made as small as possible commensurate with safety. For example, in welding a 4 x 4-in. section, only about 4 in. of sand is necessary at all points, except perhaps on the pouring gate side. It is most important thoroughly to vent the mold box by forcing a rod or wire down at a number of points to within $\frac{1}{2}$ in. or so of the collar. Care should be taken that these do not touch the collar, because such vent holes will fill with steel and will therefore not facilitate the escape of gas.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Alkaline Earth Chlorides.—Calcium, magnesium and other alkaline earth metal chlorides in anhydrous condition suitable for electrolysis are obtained by adding ammonium chloride and the oxide, hydrate, carbonate or oxychloride of the alkaline earth metal to a melt of one or more haloid salts of a metal electropositive to the alkaline earth metals, such as a mixture of sodium and potassium chlorides, and collecting the ammonia or ammonium carbonate evolved. The ammonium chloride may be 10 to 20 per cent in excess of the theoretical quantity. The ammonia or ammonium carbonate is converted into ammonium chloride for re-use by combining it with hydrochloric acid obtained by passing a mixture of chlorine and steam over carbon heated to 300 deg. C. (Br. Pat. 163,304; not yet accepted. Minami Manshu Tetsudo Kabushiki Kaisha, assignees of I. Namari, Osaka Fu, Japan; July 6, 1921.

Extracting and Separating Metals.—(The production of one salt from a mixture of oxides such as that obtained by roasting a sulphide ore is effected by submitting the mixture to the action of a gaseous acid radical under such temperature and with such pressure of the acid radical as will effect the preferential reaction desired. The invention is described in connection with the treatment of a mixture of copper and iron oxides obtained by roasting copper pyrites. This mixture is heated with sulphur trioxide under the necessary conditions at a temperature of about 620-700 deg. C., when copper sulphate alone forms. The invention is applicable to the formation of other salts such as chlorides, and to the treatment of various mixtures of oxides. The separation of copper and nickel and the extraction of aluminum salts from bauxite or other materials are mentioned. In a similar manner a mixture of salts of the same acid radical may be treated in order to effect the decomposition of one but not of the other. (Br. Pat. 163,348. W. J. Niiranen, Helsingfors, Finland, and A. Hibbert, Bexhill, Sussex; July 6, 1921.)

Casein Cements.—Powdered glue or gelatine is incorporated with the normal constituents of a casein cement in powder form. A material such as an alkali salicylate,

benzene or naphthalene sulphonate, may be added to facilitate the solution of the glue in cold water. An example is given of a powdered cement containing casein, lime, gelatine or glue, sodium fluoride and sodium naphthalene sulphonate. (Br. Pat. 163,349. P. H. W. Serle, London; July 6, 1921.)

Distilling Waste Grease.—Waste roll or axle grease or pitch obtained from steel-works, tin-plate rolling mills, etc., is distilled to obtain oils and greases, and, in some cases, a residue of coke. The waste grease is melted in a primary

still 4, from which the vapors are led by a pipe 9 to a condenser. The melted grease is drawn off by a perforated pipe 10 to a main still 7. The vapors pass to a condenser in which, by means of cocks, alternative passages may be opened. The light vapors are passed through pipes 18, 19 and a coil 20 immersed in a cooling tank 16. The middle vapors are passed through pipes 14, 15 and a pipe 17 in the cooling tank and the heavy vapors through pipe 18 and an exit pipe 21. A tank containing a freezing mixture may be used to condense very light vapors. Air may be injected into pipe 13 to assist in condensing the heavy vapors. Stirrers 5, 26 are provided in the stills 4, 7. The liquid residue from the still 7 may be distilled in a separate still to form coke. (Br. Pat. 163,056. L. Lane and D. H. Williams, both in Glamorgan; July 6, 1921.)

Electric Welding.—Thick metal plates or sheets, etc., are electrically welded by two pairs of intermittently rotated roll or wheel electrodes, current being on only when they are stationary. The work may be fed between the electrodes, or the electrodes traversed over the work. The pairs of electrodes may be arranged in tandem so that the parts left unwelded by one pair are welded by the second pair or they may be arranged so that the axes of the upper electrodes and also those of the lower electrodes are coincident, the two

lower electrodes in this case being practically in one. In the former case the shafts may be spaced well apart or may be close together so that the welds partly overlap. The upper electrodes are connected to the terminals of the transformer secondary, and the lower electrodes are electrically connected together. In the tandem arrangement shown, the upper electrodes 2 are mounted in a carrier 4 pivoted at 5 to the slide 6 so that they always bear evenly on the work. The slide is operated by a toggle 8, rod 9, bell-crank 10 and rods 27 from the shaft 11. The electrodes are rotated inter-

mittently by spur and worm gear through a shaft 17, which is rotated by gearing through a ratchet wheel 18 operated by a pawl lever 19 from a crank-shaft 14 through rods 22, 23. The current is put on when the electrodes are stationary by a switch 12, operated by a cam on the shaft 14, which is driven by a belt from the shaft 11. The electrodes are further pressed down when the welds are made to put the welds under pressure. (Br. Pat. 163,083. British Insulated & Helsby, Charles Ltd., and L. B. Wilson, Prescot, Lancashire; July 6, 1921.)

Converting Oils and Fats Into Triglycerides.—Fatty acids, or oils or fats containing free fatty acids, are converted into triglycerides by heating with glycerine to a temperature of 200-250 deg. C., whereby the glycerine reacts in the vapor state. According to one method of procedure, the glycerine contained in a still *a* is carried over by superheated steam into a vessel *b* containing the fatty acid or oil or fat containing free fatty acid, the superheated steam being admitted to the vessels *a*, *b* by pipes *j*, *k* connected with the main pipe *e*. Both vessels are provided with heating coils *c*, *d* and are subjected through pipes *m*, *n* to the action of a vacuum pump. In an alternative method, the glycerine is introduced in the liquid form into the bottom of a still containing the fatty acid material heated to the requisite temperature; in this case, an addition of 2 per cent of water

to the glycerine favors its vaporization. Any known catalyst may be employed, together with means for agitating the material. Mono- and di-glycerides can be produced by combination with the requisite amount of glycerine vapor. (Br. Pat. 163,352. E. R. Bolton and E. J. Lush, both of London; July 6, 1921.)

Ammonium Salts.—Residual liquor from the ammonia-soda process containing principally ammonium chloride and carbonate and sodium chloride is heated to near its boiling point until all the ammonium carbonate and free carbon dioxide are evolved. The ammonium carbonate or mixture of carbonate and bicarbonate is collected in the solid condition; preferably carbon dioxide is introduced if necessary so that all the ammonium is in the form of bicarbonate. The liquor is concentrated to one-third to two-thirds its volume and cooled to below 25 deg. C., when technically pure ammonium chloride crystals are obtained. After filtration, the mother liquor is again concentrated at its boiling point to one-third to two-thirds its volume, in order to separate sodium chloride. The latter is removed as nearly as possible at 110 deg. C., the boiling point of the solution. The liquor now contains ammonium chloride and sodium chloride in approximately the same proportion as the original solution and may be treated as above described, but preferably fresh residual liquor is first added. The ammonium chloride contains only small quantities of sodium chloride and is suitable as a manure, but it may, however, be purified by recrystallization or sublimation. (Br. Pat. 164,001; not yet accepted. Elektrizitätswerk Lonza, Basel, Switzerland; July 20, 1921.)

Soluble Silicates.—Soluble silicates of high silica content are prepared by dissolving silicic acid in alkali silicate solutions obtained by fusing silica and alkali, or silica, alkali and borax, and treating the cooled and broken melt with water. The silicic acid is prepared, for example, by adding sulphuric acid to cold water-glass solution and after dialysis is dissolved in the silicate solution, by continued grinding or agitation. (Br. Pat. 163,877. F. J. Phillips, London; July 20, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Special Duties Continued on Coal-Tar Products and Dyes

Title V of the Act of Sept. 8, 1916, entitled "An act to increase revenue and for other purposes," imposing duties on dyes and other chemical coal-tar products, contains the following provision in section 501:

During the period of five years beginning five years after the passage of this act such special duties shall be annually reduced by 20 per centum of the rate imposed by this section, so that at the end of such period such special duties shall no longer be assessed, levied or collected; but if, at the expiration of five years from the date of the passage of this act, the President finds that there is not being manufactured or produced within the United States as much as 60 per centum in value of the domestic consumption of the articles mentioned in Groups II and III of section 500, he shall by proclamation so declare, whereupon the special duties imposed by this section on such articles shall no longer be assessed, levied or collected.

As a result of the coal-tar censuses taken by the Tariff Commission, the commission was able to report to the President that the domestic production of the articles enumerated in Groups II and III is much in excess of 60 per cent of the domestic consumption. The facts, therefore, do not call for the issuance of a proclamation removing the specific duties under section 501 of the act cited above.

Government to Study Helium Production

An engineering study of the whole subject of helium recovery at the Petrolia plant is to be made by a board of engineers which has been named by Director Bain of the U. S. Bureau of Mines with the approval of the Army and Navy Helium Board. M. H. Roberts, formerly chief engineer of the Air Reduction Co., is chairman of the board of engineers. The other members are R. C. Tolman, head of the Fixed Nitrogen Laboratory of the Department of Agriculture, and Prof. W. L. DeBaufre of the University of Nebraska, formerly an instructor at the U. S. Naval Academy.

The large-scale operations at Petrolia, Tex., have been discontinued due to the reduction made by Congress in the appropriation for this work. It is the intention to continue the study on a small scale along the lines which will be designated by the new board of engineers.

In the fiscal year ended June 30, 1921, the Army transferred \$545,200 to the Bureau of Mines for helium work. During the same period, the Navy transferred \$207,500 to the Bureau of Mines for the same purpose. The allocation of the fund was as follows: operation and maintenance of helium plant No. 3, at Petrolia, Tex., \$425,000; equipment of cryogenic laboratory, at Washington, D. C., \$15,000; operation and maintenance of cryogenic laboratory, \$61,000; helium laboratory, Fort Worth, Tex., \$18,000; helium storage, Pittsburgh, Pa., \$1,000; railroad repurification unit, Washington, D. C., \$25,000; helium repurification plant, Langley Field, Va., \$42,700; helium gas leasing fund, \$150,000; co-operative work at Massachusetts Institute of Technology, \$3,000; co-operative work at Harvard University, \$2,000, and for other helium work, \$10,000.

Phosphates in Morocco

Five hundred tons of phosphates from Onedzem are now being shipped weekly to France. It is estimated that the yearly output at Onedzem will reach 500,000 tons in 1926, 1,750,000 tons in 1930 and 3,000,000 tons in 1940.

Germany Advances Prices of Dyes

Manufacturers in Germany have advanced the prices of dyes for silk piece goods 300 per cent.

Appointment of Chemistry Chief to Be Delayed

In all probability no nomination will be made until after the first of the year to fill the vacancy made by the resignation of Dr. Carl L. Alsberg as chief of the Bureau of Chemistry of the Department of Agriculture. Despite earnest efforts on the part of Dr. E. D. Ball, Assistant Secretary of Agriculture, who is handling the matter, no properly qualified chemist has been found who is willing to take the place at the present salary of \$5,000. As a result of that situation, it is understood that an appropriation of \$7,500 will be asked. No action on such an appropriation is likely before March. Last year the appropriations committees declined to increase the salaries of any one position until a report could be had from the reclassification committee. When that report is in hand it is expected that there will be a uniform increase in the salaries of all heads of bureaus, as well as in many subordinate positions.

Protest Spanish Tax on Pyrites

Spain's proposal to place an export tax of eight pesetas per metric ton on iron pyrites is receiving active attention at both the State and Commerce Departments. Informal protests already have been filed with the Spanish Government and the matter has been discussed extensively by the Spanish Ambassador to Washington and representatives of the sulphuric acid industry. A decision by the Spanish Government is expected before the end of September. If it should be decided to impose an export tax on pyrites of even as much as \$1 per ton, it would act as a very decided stimulus to the domestic sulphur industry and probably would encourage considerable activity in the mining of pyrites in the United States.

Ask Embargo on Chemical Stoneware

The manufacturers of chemical stoneware have joined in submitting a brief to the Finance Committee of the Senate asking that their products be protected by a duty of 200 per cent, which they admit to be practically an embargo. The tariff bill as passed by the House provides a duty of 35 per cent ad valorem on chemical stoneware, chemical porcelain and other vitrified wares. The manufacturers of stoneware contend that their industry is relatively of as great importance as is the dye industry, since carefully and laboriously made stoneware is absolutely essential in the handling of acids, alkalis and other chemicals. It was pointed out that no machinery is used in this industry except in the grinding of the clay. Labor, which must have a special expertness, represents more than 80 per cent of the total cost of the finished product. It was contended that chemical stoneware should be taken out of the paragraph containing porcelain and other vitrified ware and placed in a paragraph by itself.

American Wood Preservers' Association Establishes Service Bureau

To promote the use of wood properly treated to resist decay, marine borers and insect attack, thereby aiding in the conservation of the forest resources of the nation, the American Wood Preservers' Association has established a Service Bureau.

The value of wood for construction purposes is fairly well understood, but for permanent structures treatment with a standard preservative, such as creosote or zinc chloride, is absolutely necessary. The policy of the Service Bureau is to give the public reliable information on the treatment of timber according to the standards of the American Wood Preservers' Association, and on the use of treated wood. The bureau is located at 1146 Otis Building, Chicago. P. R. Hicks is secretary-manager.

T.A.P.P.I. Meeting

A joint meeting of the Technical Association of the Pulp and Paper Industry and the American Pulp and Paper Mill Superintendents' Association will be held at Washington, Oct. 18 to 21, with headquarters at the New Willard. The preliminary program follows:

TUESDAY, OCT. 18

9 a.m.—Assemble at Industrial Building of the Bureau of Standards for reading and discussion of papers in general and group meetings arranged by T.A.P.P.I. Service Committee, and committee of A. P. & P. M. S. A.

12:30 p.m.—Luncheon, Bureau of Standards.

2 p.m.—Inspection of sections of the Bureau of Standards; visit to paper and dye laboratories of the Bureau of Chemistry; optional visits to Government Printing Office, Bureau of Engraving and Printing, and mill of District of Columbia Paper Manufacturing Company.

7 p.m.—Supper at New Willard Hotel, followed by smoker, and continuation of papers, group meetings and discussions.

12 m.—Take Pullman cars for York, for visits to York, York Haven and Spring Grove, Pa.

WEDNESDAY, OCT. 19

Mill and plant visitations in York, York Haven and Spring Grove, Pa. Leave Washington for York, Pa., by midnight train. Breakfast on arrival at York. Visits to plants in York and York Haven, followed by trip to Spring Grove in afternoon. Leave York for Philadelphia in evening.

THURSDAY, OCT. 20

Breakfast in Philadelphia at Bellevue-Stratford, association headquarters, where members and guests will register for visits to the various mills and plants to be inspected during the day.

7 p.m.—Banquet at Bellevue-Stratford.

FRIDAY, OCT. 21

Excursion to Wilmington, Del. Leave Philadelphia for Wilmington by early train. Breakfast at cafeteria of Pusey-Jones Co. on arrival, followed by visits to plants as follows: Pusey-Jones Co., du Pont Co.'s plant at Carney's Point, inspection of laboratory and dye works of the du Pont Co.

Naval Stores and Fertilizer Movement for the Past Fiscal Year

The data on the movement of naval stores—rosins and turpentine—show a marked decrease in the demand for domestic rosins, with almost as great an increase in the call for our turpentine, as compiled by the Bureau of Foreign and Domestic Commerce for the fiscal year ended June 30.

During the past three years American rosin was purchased abroad to the following extent: 881,777 bbl., valued at \$11,323,381, in 1919; 1,322,034 bbl., valued at \$24,847,691, in 1920; and 877,160 bbl., valued at \$10,364,804, in 1921. The decrease in quantity during the past year was 34 per cent; the average price per barrel, however, dropped from \$18.80 to \$11.82. During the month of June there was a noticeable increase in this product and exports advanced from 70,938 bbl., valued at \$1,306,279, for June, 1920, to 101,189 bbl., valued at \$516,791, in 1921. The price one year ago was \$18.79 per bbl. For June, 1921, it averaged \$11.82.

The sales for export on our spirits of turpentine amounted to 8,064,578 gal. (\$6,069,853) in 1919, 7,461,355 gal. (\$11,121,864) in 1920 and 9,741,711 gal. (\$11,279,353) in 1921. The increase during the past year was 30.7 per cent. The price per gal. averaged \$1.49 in 1920 and \$1.16 during the past fiscal year. A pronounced increase in shipments of turpentine was recorded in June. A year ago figures for the month were 360,213 gal., valued at \$664,655. In June, 1921, there was 1,477,416 gal., invoiced at \$867,302. The export price of \$1.84 per gal. in June, 1920, fell to 59c. in June, 1921. Great Britain takes 53 per cent of our shipments of turpentine; Canada is next with 9.6 per cent. Other leading markets in decreasing order of importance are Holland, Belgium and Argentina. Great Britain is also the leading market for American rosin, purchasing 33 per cent. Brazil takes 14 per cent, Argentina 12 per cent, Canada 9.6 per cent and Australia 4.6 per cent.

Tar, pitch and minor naval stores were exported to the extent of 48,008 bbl., valued at \$384,263, during the fiscal

year 1919; 61,790 bbl. (\$534,175) in 1920, and 41,864 bbl. (\$380,267) in 1921. In June, 1921, the exports in this class were 2,098 bbl., valued at \$15,857, as compared with 5,357 bbl. (\$49,730) during the previous year.

The total value of our exports of naval stores amounted to \$17,777,497 in 1919, \$36,503,720 in 1920 and \$22,024,424 in 1921. In the fiscal year 1913-1914 it was \$19,882,165.

In volume our shipments of rosin for the past year were 36 per cent of the exports of seven years ago. Turpentine shipments are now but one-half those recorded just before the war. Tar and pitch have dropped 88 per cent.

The fiscal year figures covering the fertilizer materials show a slight gain over the previous year. During the month of June, however, the imports became practically negligible, while the exports were about one-third the value and two-thirds the volume for the same month in 1920. In the latter month we exported 112,708 long tons of fertilizers valued at \$2,862,688. In June this year the shipments were 75,391 long tons, valued at \$971,757. The heaviest reductions were in ammonium sulphate and miscellaneous fertilizers and also in superphosphates, which fell from 1,038 to 70 tons. Raw phosphate rock decreased 23 per cent. Imports in this group amounted to 96,796 tons in June, 1920, valued at \$3,441,616. In June of this year the total was 4,642 tons, valued at \$183,983. This downward trend was most marked in the potassium salts group. The chloride dropped from 4,811 to 10 tons; manure salts from 24,642 to 105 tons.

During the fiscal year ended June 30, 1919, we imported fertilizers to the amount of 118,236 long tons, valued at \$5,883,376; 867,623 tons (\$38,578,063) in 1920; 608,287 tons (\$28,550,111) in 1921. During the past year, as compared with the previous one, there was a decrease of 30 per cent in volume and 26 per cent in value. The drop is less than that for chemical products in general, which is 30.5 per cent. Some increases in the volume of imports are recorded. Potassium sulphate and guano doubled; bone in various forms advanced from 7,340 to 27,413 long tons; on the other hand, calcium cyanamide dropped 50 per cent; manure salts 51 per cent; potassium chloride 55 per cent.

There was a drop of 24.8 per cent in the value of fertilizers exported during the fiscal year 1921. The outward movement in 1919 was 346,944 long tons (\$9,405,242); in 1920 it reached 1,129,369 tons (\$33,243,411); in 1921 it totaled 1,147,864 tons, of a value of \$24,969,271. Superphosphates lost 68 per cent, and ammonium sulphate dropped 58 per cent in quantity and 40 per cent in value. Ammonium sulphate itself has become a leading factor in our fertilizer exports. During the past year it constituted 30 per cent of the total value. Noteworthy is the movement of ammonium sulphate. During 1913-14 we imported 74,440 tons. In the fiscal year just ended our imports were 2,537 tons, while we shipped abroad 65,915 tons—almost as much as we purchased from Europe seven years ago.

New Navy Wage Scale Fixed

The Navy Wage Board has recommended and the Secretary of the Navy has approved a new schedule of wages for all the employees of the navy establishments. The schedule for chemists ranges from \$10.56 per day to \$7.20 per day. Chief chemists are to receive \$11.36 per day. Assistant chemists are to receive from \$6.88 to \$4.88. Chief metallurgists are to receive \$3,000 per annum. Assistant chief metallurgists are to receive \$8.32 per day. Chemical laborers are to receive \$5.36 and \$4.56 per day.

Ford Invited to Washington

The Secretary of War has invited Henry Ford to come to Washington to discuss Mr. Ford's proposal to take over the Muscle Shoals water power project and nitrate plant. At the time of this writing, Secretary Weeks had not heard whether or not Mr. Ford will accept the invitation.

India Imposes Export Tax on Lac

The government of India has approved the imposition of a small export tax on lac, in order to finance research work in connection with the lac industry.

A bill authorizing the tax will be introduced in the ensuing session of the Indian Legislature.

The Ceramic Station of the Bureau of Mines Investigates Industrial Burning Problems

The Ceramic Experiment Station of the U. S. Bureau of Mines has entered into a co-operative agreement jointly with the Common Brick, Face Brick, Paving Brick and Hollow Building Tile Associations, in order to investigate problems in connection with burning clay products. The ultimate objects of the work are to conserve fuel, shorten the time of burning and improve the qualities of the products.

The four clay associations have contributed a joint fund of \$10,000 for the investigation. Of that sum \$7,500 has been allotted to the Ceramic Experiment Station of the Bureau of Mines for making field investigations on industrial kilns. In addition to this sum the Bureau of Mines purposes to spend \$15,000 or more.

The kiln investigations will consist in obtaining data on fourteen or more kilns to determine the amount of fuel used, the amount of ware placed in the kiln, temperatures at three different levels during the process of burning, temperature of the flue gases, analysis of the flue gases, the end point of water smoking, the end point of oxidation, length of time for burning, analysis of the fuel and ash, drawings of the kilns showing dimensions, their age and condition as to repairs. From the study of the data obtained changes in the construction of the kilns, the shortening of the time of burning and change in method of setting and firing are to be made. From isolated cases where similar kiln studies have been made as much as 0.5 ton of coal per 1,000 brick has been saved and a shortening in the time of burning of as much as 25 per cent. On a plant of 20,000,000 annual brick capacity it is possible to make a saving of from 5,000 to 10,000 tons of coal annually. This is especially true in plants where firing conditions are exceptionally bad.

The work will be under the supervision of R. T. Stull, chief ceramist of the bureau, who has placed three ceramic engineers on the field work. In connection with the field studies the services of the fuel section of the bureau will be available and the services of a fuel engineer will be placed on the work for at least six months. Laboratory studies are also to be made at the ceramic station on oxidation and vitrification problems.

Transportation of Dangerous Materials

Effective Sept. 1, the Interstate Commerce Commission has placed amended regulations in force governing the transportation of arsenic, paris green, arsenate of lead, calcium arsenate and other such materials. Such articles must not be offered or accepted for shipment in bulk, but must be packed in strong and tight containers, of type to prevent sifting or escaping of contents in transit. Permission is allowed, however, for the shipment of sintered arsenical flue dust in steel gondola cars, with suitable covers, between plants.

Radium Plants Merge

The United States Radium Co., New York, recently organized, will take over a number of the larger radium companies in this country, including the Radium Luminous Material Corp., 58 Pine St., New York, with works at Orange, N. J.; the subsidiaries of the latter company will also be included in the merger, and the Undark Radium Mines, in the Paradox Valley section of Colorado. The radium works and extraction plant at Orange will be continued in operation by the consolidated company, and also the radium research laboratory of the Undark organization. Arthur Roeder is chairman of the board of directors of the new company.

Glass Workers Accept Wage Reduction

Skilled operatives and other workers at the "hand plants" devoted to the manufacture of sheet glass have accepted a wage reduction of 28 per cent, effective Sept. 6, as a result of a series of conferences between representatives of the Window Glass Manufacturers' Association of America and the American Window Glass Workers. About 18,000 persons are affected by the reduction.

Non-Metallic Investigations of Bureau of Mines

Experimental work on cement and heavy clay products for which Congress recently appropriated \$35,000 now is under satisfactory headway at the Bureau of Mines ceramic station at Columbus, Ohio.

The Department of the Interior, which is a large buyer of cement, felt the lack of certain technical and economic data regarding the cost of raw materials, of burning and of the factors entering into quality and deterioration. At the same time the building industry was stagnant, in part because of the high cost of materials in which fuel and labor were the main items. The manufacture of the non-metallic building materials, except perhaps in the case of cement, is conducted in small scattered plants few of which have adequate technical knowledge or direction, the situation being similar in many particulars to that of the small farming industry. It is the purpose of this appropriation, at once to develop improved technology where that may be possible, and to disseminate widely among the smaller producers knowledge of the best current practice to the end that costs and wastes be reduced.

Much of this appropriation is being expended through the bureau's ceramic station at Ohio State University. A study has been started there of the technology of the cement industry, particularly as to choice of raw materials, economic use of fuel and related economic problems of transportation. To this has been allotted \$10,600 and the co-operation of the Department of Commerce has been arranged.

Other non-metallics, including the mining and utilization of feldspar, phosphate rock, slate and potash, are being studied and efforts made to reduce cost of production and utilization of byproducts hitherto considered waste. To this work \$5,700 has been allotted.

Several basic ceramic chemical problems connected with the burning of clay products will be worked out at the University of Illinois under the direction of a consulting ceramic chemist. For the carrying on of this study \$1,000 is allotted.

Society of Industrial Engineers to Meet in Springfield

One of the most important industrial meetings of the year will be the fifth annual convention of the Society of Industrial Engineers, to be held in Springfield, Mass., Oct. 5, 6 and 7. In the membership of this national organization are business executives and industrial engineers from almost every line of industry, which naturally tends to add interest to the national meetings.

Industrial stability will be the main theme for discussion, the topics on the program covering four of the major functions of industry—production, finance and accounting, sales, and industrial relations. All the speakers will be men of broad practical experience and national reputation.

Afternoon and evening sessions will be held on each of the three days, the mornings being devoted to visiting some of the most progressive plants in the Springfield district. All the sessions will be open to the public.

Uncertain as to Potash Discoveries

Every effort is being made by the United States Potash Producers' Association to ascertain the real facts in regard to the discovery of potash in two oil wells drilled in western Texas. While there is no disputing that material which carries as much potash as does the German product has been found, no information reaching the Potash Producers' Association carries with it any proof that the potash deposit is of sufficient thickness to justify the expensive mining operations which would be required to recover it. It is believed that it will require diamond drilling to get definite data as to the occurrence of potash-bearing material in commercial quantities.

British Chemical Dispute Settled

A settlement of the dispute in the chemical industry has been effected.

Metric System Hearings

A sub-committee of the Senate Committee on Manufactures has been designated to conduct hearings on a bill by Senator Ladd, of North Dakota, providing for the compulsory adoption, after ten years, of the metric system of weights and measures. Senator McNary, of Oregon, will act as chairman of the sub-committee. The other members are Senator Weller, of Maryland, and Senator Jones, of New Mexico.

It is the intention to have limited hearings shortly after the congressional recess, so that the proponents and opponents of the legislation may state their views as to the desirability of such a law. It then is the intention to circulate as widely as possible a stenographic record of the hearing, with the idea of acquainting the public with the problems involved. Later, during the regular session of Congress which begins in December, it is planned to have further hearings, after which an attempt will be made to get favorable action by the committee, thereby obtaining a place for the bill on the Senate calendar where its consideration would be taken up in due course.

Experimental Paper Mill Being Sent to Siam

As a result of tests made on the experimental paper machine at the Bureau of Standards using rice straw, banana tree stems and lalang grass from Siam, Siamese officials saw the possibilities of the paper industry in their country and their government asked the American Government, through the State Department and the Department of Commerce, to supervise the design and purchase of a similar experimental machine.

Although not intended primarily for commercial purposes, the machine which is now en route will furnish the writing and printing paper for the Siamese army. It will be erected at Bangkok, Siam, under the supervision of the Royal Survey Department of the army.

The paper mill consists essentially of a 44-in. Fourdrier paper machine, two 300-lb. beaters, a small Jordan engine, a 600-lb. rotary boiler, a cylinder duster, screen, sheet cutter, suitable pumps, shafting, pulleys and motors, bleach plant, necessary electrical fittings, and plumbing, belting and spare parts. It is capable of producing 1,200 lb. of paper per day.

Iron Industry at Buffalo Resuming Activity

A number of the iron and steel plants at Buffalo, N. Y., are resuming production on an increased scale, following a long period of inactivity. The Lackawanna Steel Co. is now operating nine of its rolling mills and adding many former employees to the working force. This company has entered the pig iron field, and is reported to have sold about 30,000 tons in recent weeks. The Wickwire Steel Co. has placed a number of additional mills in service, with increased working force, while the plant of the Seneca Iron & Steel Co., at Blasdell, near Buffalo, is again in operation after a period of idleness. Production is still curtailed at the local works of the Rogers, Brown Co.

Hungarian Banks Organize Company to Manufacture Artificial Manures

Some of the largest Hungarian banks have organized a company for the purpose of transforming Magyarovar Munitions Works into a plant for the manufacture of artificial manures.

Duties for Non-Metals Asked

One of the features of the hearings before the Finance Committee of the Senate has been the particularly strong pleas that have been made for protection sufficiently high to allow the domestic mining of the non-metals to flourish.

Few Purchases of Heavy Chemicals in Brazil

Due to the uncertainty as to exchange, few purchases of heavy chemicals are being made in Brazil, say cable advices to the Department of Commerce.

Glass Plant Operations in West Virginia

Despite the decreased demand for flint glassware during recent months, the different plants of this character in the Wheeling, W. Va., district have been making a number of improvements and expanding their works. The slack period of the past eight weeks particularly has been used to good advantage in this direction. The majority of the plants are now in condition to meet all expected demands, and the general situation in the industry is showing noticeable improvement.

The cut glass and gift glassware plants in this section report an increased volume of business and large number of inquiries for material for fall and holiday trade. Blown and etched tableware glass plants also are receiving larger orders, and current business is better than for a number of months past.

Bottle and jar manufacturers in the district have been engaging on an improvement program during recent months, with a number of plant extensions and betterments, as well as repairs to machinery and equipment. This branch of the glassware industry reports an increased demand for material. Plants devoted to the manufacture of lamp chimneys and kindred glassware have been operating on a much curtailed schedule for the past three or four months, with present indications that production can be resumed on a near-normal basis at an early date.

Glassware for lighting service is showing an improved demand, and plants engaged in this line are commencing to increase production in anticipation of a good holiday business.

Artificial Leather From Cordite

Following experiments and investigations for a year past, the chemical department at the plant of the Ford Motor Co., Detroit, Mich., has perfected a process for the manufacture of artificial leather from cordite gunpowder, a high explosive. The new development will be utilized at the leather works of the company at once. It is said that a purchase of 857 carloads, or about 35,000,000 lb. of the material has been made from the British Government, at a price less than one-fifth of the war-time value of cordite. It will be transferred to the Highland Park works in such quantities as needed for artificial leather production. The new process is stated to reduce the cost of manufacture about one-half. The local plant of the company has an average output of about 25,000 sq.yd. of artificial leather per day, the entire production being used on Ford automobiles.

Internal Revenue Collections

An analysis of internal revenue collections during the fiscal year ended June 30 shows that the tax on perfumes, cosmetics and medicinal articles produced \$5,800,768.41. This shows a slight decrease from the revenue derived from these sources during the preceding fiscal year, when it was \$6,427,881.08. The levy on toilet soap and toilet soap powders produced \$2,223,773.99. This is an increase over the collection during the fiscal year ended June 30, 1920, when collections under that head totaled \$1,919,398.44. The tax on importers, manufacturers, compounders and dealers in opium, coca leaves and their salt derivatives, including the tax on the product, amounted to \$1,161,174.12. In the preceding fiscal year the collection from the same sources was \$1,153,919.50.

British Columbia Paper Plant Reopens

The Whalen Pulp & Paper Co. reopened its plant at Wood Fibre, B. C., on Aug. 15. This plant of the Whalen company produces only pulp suitable for the manufacture of book paper; the demand for this class of pulp fell off early in the season, and the plant was closed. T. W. McGarry, president of the company, states that conditions now have improved, and it is expected that the Wood Fibre plant will be worked at capacity and will give employment to about 300 men. The Whalen company's Port Alice plant, which produces pulp for newsprint paper, has been working at capacity and turning out 1,800 tons of pulp weekly. The Reliance Mill & Trading Co. has retired from the management of the Whalen company's plants.

Personal

HAROLD W. ABBOTT, former technical supervisor at the Massena plant of the Aluminum Co. of America, has accepted a position along the same lines in the research and development division of the Stackpole Carbon Co., St. Mary's, Pa.

Dr. RAYMOND F. BACON has resigned as director of Mellon Institute to take effect Jan. 1, 1922. Dr. E. R. Weidlein has been appointed acting director.

OSCAR H. BETTS has been elected president of the Bethlehem Paper Co., Bethlehem, Pa.

H. S. BOUTELL has been elected treasurer of the Detroit Graphite Co., Detroit, Mich., succeeding W. F. Monroe, resigned.

C. S. BRYAN has become connected with the Provident Chemical Works, St. Louis, Mo., as chemical engineer. He was for several years with the Virginia-Carolina Chemical Co. as superintendent and research chemist, and more recently has been acting as manager of the Charleston Chemical Co., Charleston, S. C.

Dr. F. G. COTTRELL, head of the chemical activities of the National Research Council, will sail from France on Oct. 11 on his return to the United States. Dr. Cottrell has spent the summer in Europe studying various phases of the chemical industry. Among other things he paid particular attention to the liquefaction of gases.

O. D. CUNNINGHAM has become connected with the physical chemistry department of the plant of the Republic Creosoting Co., Indianapolis, Ind., to engage in research work. He was engaged formerly in a similar capacity at the plant of the National Aniline & Chemical Co., Buffalo, N. Y.

Dr. F. A. GILGILLIAN has become connected with the research department of the Calco Chemical Co., Bound Brook, N. J.

RALPH C. HOLDER recently resigned as junior chemist in the food research laboratory, Bureau of Chemistry, to accept a position as chemist in charge of the chemical laboratory for the Collis Products Co. at St. Paul, Minn.

B. B. GOTTSBERGER was recently elected secretary of the Mining and Metallurgical Society of America, and assumed the duties of that position on Aug. 1.

H. B. MYERS has resumed his position as head of the finishing department at the plant of the Hartford City Paper Co., Hartford City, Ind., after an absence of about ten months, during which time he has been connected with a paper mill at Bryn Mawr, Pa.

JOHN F. SLEEPER, author and chemist, is retiring to his fruit ranch at Santa Barbara, Cal., and leaves his home in Tenaflly, N. J., the middle of September.

Dr. REUBEN S. TOUR, Government chemical expert, has been appointed professor of chemical engineering at the University of Cincinnati, Cincinnati, Ohio, succeeding Dr. O. R. Sweeney, who resigned because of ill health. Dr. Tour will continue as a consulting expert for the Government. His new duties began Sept. 1, 1921.

Obituary

CHARLES H. FOOTE, well known in the steel trade as an officer of the Illinois Steel Co. for a number of years, died on Aug. 28 at Burlington, Vt., aged seventy-nine. Mr. Foote leaves two daughters, and a son, Thomas W. Foote, of Cleveland.

WILLIAM VOGEL, of Proffit, Va., secretary-treasurer of the Ohio Sulphur Mining Co., died at the University Hospital, Charlottesville, Va., Aug. 17, from peritonitis.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Sept. 12, 1921.

Chemical trading continues to show a gradual improvement, especially in the fertilizer trade, where firmer prices have been reflected. Miscellaneous inquiries have been freer and more business is passing through export channels, particularly to South America, Japan and some European centers. This clearly indicates that large surplus stocks held by these countries have finally been absorbed and that a steady expansion in trade may be expected to develop in the near future. Increased production at some of our largest caustic soda and soda ash plants is an extremely optimistic sign and bids fair to dispel some of the gloom surrounding these items. Ammonium sulphate is in strong demand in view of the limited supplies available. The activity of fertilizers has resulted in greater activity in sulphuric acid and this has reflected itself in other directions in the heavy chemical market. While general trading is not very broad, the market is beginning to feel the stimulating influence of inquiries from the paper, textile, glass, tanning and other consuming industries. Sales all around are larger than a month ago and more transactions are noted. Those close to the pulse of trading expect a good volume of business during the last quarter. Outside developments have been quite favorable. Our export trade is showing a spark of real snappy improvement. Sound and effective measures have been provided for the farming industry. The only thing that is keenly awaited is a wise tariff policy.

CHEMICALS

Prices on *caustic potash* have recently been advanced and some of the largest sellers are refusing to shade 4½c. per lb. for either spot or forward shipments of the imported 88-92 per cent. It is stated that a few odd lots might still be purchased at 4½c., but the tone of the market is decidedly firmer. There were rumors that some producers abroad have stopped making this product on account of the relatively low price. Spot *bichromate of soda* was quoted at a higher price in several directions and the general range was 8@8½c. per lb., although a few small lots might be purchased at a slight concession. The movement at present is confined chiefly to small quantities, as consumers appear satisfied to operate very cautiously.

Buying orders on *ammonium sulphate* have been in the market during the past week from Japan and Spain and large lots of sulphate have been moved out on them. The consequence has been a rise in the export price to \$2.40 per 100 lb. in double bags, f.a.s. New York. Makers are unable to quote for prompt delivery, but name a nominal price of \$1.90 per 100 lb. for bulk sulphate at the works. Prices on *barium chloride* are weakening on competition among importers. The price of \$45 per ton for spot goods can probably be shaded considerably for firm business in quantity. The resale *bleaching powder* market is stiffening as stocks keep moving. The quoted price of \$2.05 per 100 lb., f.o.b. works, is becoming increasingly hard to do. Makers quote 2½c. per lb. for prime bleach at the plant. Spot prices are around \$2.60 per 100 lb.

Dealers of solid *caustic soda* quote \$3.85 per 100 lb. at the works, while spot material of standard make is held at \$3.90@\$4 per 100 lb., with sales reported at \$3.95. Additional export business of moderate dimensions went through at 4c. per lb., f.a.s. New York, for South America. Producers are holding the market steady at 3½c. per lb., basis 60 per cent, f.o.b. works, in carload lots. The tone of the general market may be described as steady. A slow demand for *copper sulphate* has forced importers' prices down to 5c. per lb. on spot. In the absence of any noticeable business, makers have not reduced their prices below 5½c. per lb. Large lots of *hyposulphite of soda* are quoted at \$3.40 per 100 lb., while small lots on spot have commanded up

to 3½c. per lb. The market remained steady. Demand for spot *prussiate of soda* is active enough to hold the market firm at the late advance. While 12½c. per lb. might be done in some quarters, in others 12¼c. was quoted. Spot supplies are not heavy and it is said to be doubtful if prompt shipment can be purchased at prices much below those prevailing in the spot market. Dealers are holding light *soda ash* in single bags at prices ranging from \$2.05@\$2.15 per 100 lb. on spot. Sales of barrels have been reported by second hands at \$2.45@\$2.50 per 100 lb. The tone of the market is firm, with a better inquiry reported by both makers and dealers. At the works \$1.60 per 100 lb. is named for single bags in carload lots, basis 48 per cent. Fused 60-62 per cent *sodium sulphide* is moving at 4½c. per lb. for the imported grade. In one quarter the sale of 100 tons at this figure was noted. Small lots are quoted up to 5c. per lb. The broken variety is quoted at the same price as fused. Domestic producers quote fused at 5¼c. per lb. in carlots and broken at 6c.

Commercial *white arsenic* is quoted on the spot at 6¼@6½c. per lb. The movement of late has been rather quiet and the tone has been a shade easier on account of the absence of support. *Red arsenic* is also moving quietly at prices ranging from 11@12c. per lb. Producers of *formaldehyde* report sales at 12@12½c. per lb. in barrels, f.o.b. works. The spot market is quoted at 12½@13c. per lb. in most directions. A moderate inquiry is reported, with some first hand sales at the inside figure. Sales of technical *magnesia carbonate* in bags are reported on the basis of 8½c. per lb. Sales of barrels are reported at 9½c. Kegs are quoted up to 10½c. Irregular activity is noted in the market, with consumers buying only actual wants. Spot *oxalic acid* is quoted from 16@17½c. per lb., depending upon the quantity, brand and seller. The best open price given by producers is 16c. per lb., at the works, although it is understood that actual sales have gone through a shade under this figure. Small lots are attracting the attention of consumers and in the aggregate a fair volume of business is passing.

COAL-TAR PRODUCTS

Considerable improvement was noted in the general list of coal-tar products during the past week. Consumers are taking on supplies to cover their requirements at least until the expiration of the emergency tariff and in this way quite a volume of business has been done. The intervention of the holiday had some effect in limiting the number of buying orders, but in spite of this, prospects for the immediate future are much brighter than a few months ago. The financial weakness of some makers of intermediates has forced sales at reductions, but as a rule prices are holding well. Resale *benzene* is very difficult to find and prices are well above refiners'. The 90 per cent has sold at 38c. per gal., with 40c. quoted for c.p. Refiners are offering only for future delivery at 27@33c. per gal. for c.p. and 25@31c. for 90 per cent. The English market for *cresylic acid* is holding firm. Spot supplies are sufficient to take care of the present demand, but any sustained inquiry would deplete stocks considerably and probably lead to higher prices, as replacement costs are above present selling levels. Insecticide makers are displaying interest and most of the present buying is being done by them. The 97@99 per cent is quoted at 70@75c. per gal., with the 95 per cent at 60@65c. per gal. The demand for *toluene* is moderately active and the scarcity of benzene tends to strengthen the market. Resale goods are selling at 36@40c. per gal. in

drums with refiners quoting 27@34c. per gal. Prices on *phenol* are quoted lower on light demand. Resale offers of limited quantities are heard down to 8¼c. per lb. Resale stocks of *aniline oil* are large and competition among sellers is keen. Business is still passing at 18@18½c. per lb., although producers' lowest figures are 20c. A fair amount of small-lot buying is being done, but round lot sales are infrequent. Sellers of *aniline salt* quote from 25@28c. per lb. The demand is confined to small quantities, with practically no export business recorded. A slight improvement is noted in the demand for *dimethylaniline*. Resale goods are held at 43@45c. per lb. with first hands asking up to 50c. The lowest quotation heard on *diphenylamine* is 62c. per lb., with 75c. asked in some directions. The demand is slightly better, but it is mostly small-lot orders that are being booked.

WAXES

There was a firm market for both crude and refined *beeswax*. African crude on spot closed at 16@16½c. per lb., while on forward business the ideas of sellers ranged from 14½@15c. per lb., depending upon the quantity. Brazilian crude held at 22@24c. per lb. Pure white refined was quotably unchanged at 36@42c. per lb. Offerings of *Carnauba wax* were not pressing, and with reports from primary centers holding steady, quotations were well maintained on a basis of 25@26c. per lb. for the No. 2 North Country, with No. 3 North Country slightly lower, at 14½@15c. per lb. The spot situation in *Japan wax* was strong and for small quantities prices as high as 25c. per lb. were paid. For goods to arrive the market ranged from 21@22c. per lb. Futures were firmly maintained, leading factors quoting from 18@19c. per lb., according to brand and quantity. The general spot quotation ranged from 24@25c. per lb. The export inquiry for *paraffine wax* has shown slight improvement, but with stocks on hand liberal, selling pressure continues and prices present a rather unsettled appearance. Crude *scale wax* of 122 to 124 degree melting point was available at 1½c. per lb., carload lots, prompt shipment from works. *Match wax* held around 3¼@3½c. per lb., barrels included.

The Iron and Steel Market

PITTSBURGH, Sept. 9, 1921.

Scrutiny of details as to the buying and selling of steel mill products, with an open mind, leads to a clear conception of the underlying conditions and the prospects for the nearby future, while attempts to appraise the present steel market in the light of market "movements" before the war bring only confusion. Such confusion is disclosed in much of the comment that is made in relatively uninformed quarters, where what may be called criticism of the present steel market is indulged in.

Thus it is impatiently remarked sometimes that there is "no forward buying" of steel products, as if nothing could be good or encouraging in steel without the performance indicated. The steel mills had an average operation of less than 20 per cent of capacity at the middle of July, and their owners put many things ahead of a desire to have a full operation Christmas week. In the market movements before the war much of the forward buying was predicated not so much upon requirements the buyer was assured he would have as upon a belief that prices were going to advance. First, prices were allowed to go too far down. Then buyers were permitted to buy at those prices for prompt delivery. Next they were permitted to contract a short time ahead at a slight advance. After a short time another advance would be made, and buyers would be permitted to "cover" for an additional period. This was the regular performance, and it was prolonged until it became top heavy. One must not expect that sort of thing now. The desire of steel producers is not to advance prices above the present level, but to reduce costs.

Then there is complaint that the Steel Corporation's "unfilled tonnage" does not increase when it is reported that more steel is being bought. The condition, of course, is that the corporation has contracts with nearly all its customers, these contracts being represented in the "unfilled tonnage" reported month by month. The orders the

corporation receives are chiefly specifications against these contracts. The more business the corporation receives the more tonnage it ships and the more its unfilled obligations decrease. If bond interest and dividends are to be paid, they will be paid by the steel that is shipped and paid for, not by the contracts that fail to be specified against. The July decrease in the "unfilled tonnage" was less than the June decrease, because the corporation shipped less steel.

PRODUCTION

There has been a slight upward trend in the production of pig iron in the past few weeks, but a more distinct increase is to be expected in the next few weeks. The rate now is about 25 per cent of the actual capacity. Steel ingot production is increasing, in general, but at a very slow rate, production being now in the neighborhood of 30 per cent of capacity, this being fully one-half greater than production at the low point, about the middle of July.

Tonnage output, however, is not an altogether fair criterion as to the improvement that has been occurring in fundamental conditions relating to steel demand, for the reason that the increase in demand has been almost wholly in the lighter finished steel products, particularly sheets, tubular goods, tin plate and merchant bars, where a given tonnage means more than a similar tonnage in plates, shapes and rails, which have shown scarcely any improvement.

The American Sheet & Tin Plate Co. (Steel Corporation) had last week both the largest volume of orders and specifications and the heaviest shipments of its products, tin plates and sheets, for any week since last April, and for this week it has scheduled a 50 per cent operation for both sheet mills and tin mills. There was a time recently when there was only about a 25 per cent operation in each class. Bookings of the pipe mills were 30 to 35 per cent greater in August than in July. Merchant steel bars showed a smaller improvement.

Demand for steel for construction purposes has had its ups and downs, with no important improvement plainly marked. Just at the moment it would appear that the trend is distinctly upward, but on account of the season of the year no great amount of reliance should be placed on this showing.

STEEL PRICES

Bars, shapes and plates can be bought at prices ranging, roughly speaking, from 1.65c. to 1.75c., depending on the size and desirability otherwise of the order offered. The range is narrower than a month or six weeks ago, and the average is but little lower. Sheets are very steady since the recent declines to 2.25c. for blue annealed, 2.75c. for black and 3.75c. for galvanized. Shading in standard steel pipe generally does not run more than \$2 a ton at the outside from the prices openly named July 9. Wire products are quite steady at prices developed two months ago, 2.50c. for plain wire and \$2.75 for nails. Altogether, while the steel market may not have struck bottom for the nearby future, it is amply near enough for safety to those who buy for nearby requirements, and no one has occasion to buy otherwise. Even for a construction job that would be expected to yield a return over a period of many years, the possible decline in prices of mill products would not be a serious drain upon annual earnings. If there is disinclination to buy steel for construction work, it is due to the cost of putting the steel into employment, or uncertainty as to earnings of the structure, rather than to the cost of the steel itself.

PIG IRON AND COKE

Pig iron continues to show, in general, a slight stiffening tendency, this being due, as previously indicated in these reports, to unexpected delay in reductions in freight rates, which would lower the cost of production, while there has been liquidation of furnace stocks. In the local market bessemer and basic are quotable unchanged at \$20 and \$19 respectively, f.o.b. valley furnaces, while foundry iron is up another 50c., to \$21 valley.

Connellsville coke has advanced 25c., to \$3.25 for furnace and \$4.25 as minimum for foundry, some brands commanding \$4.50 as hitherto.

Potassium bichromate.....lb.	11 1/2	11 1/2	12	12 1/2

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . \$. . .	\$0.28 1/2 - \$0.29 1/2
Potassium bromide, granular..... lb.		.16 - .25
Potassium carbonate, U. S. P..... lb.	.35 - .40	.45 - .50
Potassium carbonate, 80-85%..... lb.	.05 - .05 1/2	.06 - .06 1/2
Potassium chlorate, crystals..... lb.	.06 1/2 - .07	.07 1/2 - .10
Potassium cyanide..... lb.		.26 - .28
Potassium hydroxide (caustic potash)..... lb.	.04 1/2 - .04 3/4	.05 - .06
Potassium muriate, 80% K.C.I..... ton	42.50 - 45.00	
Potassium iodide..... lb.		2.75 - 3.00
Potassium nitrate..... lb.	.09 1/2 - .09 3/4	.10 - .12 1/2
Potassium permanganate..... lb.	.23 - .24	.24 1/2 - .25
Potassium prussiate, red..... lb.	.28 - .29	.29 1/2 - .30
Potassium prussiate, yellow..... lb.	.20 1/2 - .21	.22 - .22 1/2
Potassium sulphate (powdered)..... per unit		1.20 - 1.25
Rochelle salts (see sodium potas tartrate).....		
Sal ammoniac (see ammonium chloride).....		
Salt soda (see sodium carbonate).....		
Salt cake (bulk)..... ton		20.00 - 25.00
Silver cyanide..... oz.		1.35 - 1.38
Silver nitrate..... oz.		.41 1/2 - .42
Soda ash, light..... 100 lb.	2.10 - 2.15	2.20 - 2.70
Soda ash, dense..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate..... lb.	.04 - .04 1/2	.04 1/2 - .05
Sodium bicarbonate..... 100 lb.	2.25 - 2.40	2.50 - 2.75
Sodium bichromate..... lb.	.08 - .08 1/2	.08 1/2 - .09
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.04 1/2 - .04 3/4	.05 - .06
Sodium borate (borax)..... lb.	.05 1/2 - .06	.06 1/2 - .07
Sodium carbonate (salt soda)..... 100 lb.	1.90 - 2.00	2.10 - 2.40
Sodium chloride..... lb.	.07 1/2 - .07 3/4	.08 - .08 1/2
Sodium cyanide..... lb.	.19 1/2 - .21	.22 - .30
Sodium fluoride..... lb.	.11 - .11 1/2	.12 - .13
Sodium hydroxide (caustic soda)..... 100 lb.	3.90 - 4.00	4.10 - 4.60
Sodium hyposulphite..... lb.		.03 1/2 - .03 3/4
Sodium nitrate..... 100 lb.	2.10 -	2.30 -
Sodium nitrite..... lb.	.07 - .07 1/2	.07 1/2 - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.04 1/2 - .04 3/4	.05 - .05 1/2
Sodium potassium tartrate (Rochelle salts) lb.		.21 - .24
Sodium prussiate, yellow..... lb.	.12 1/2 - .12 3/4	.12 1/2 - .13
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02 - .03	.03 1/2 - .03 3/4
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04 1/2 - .04 3/4	.05 - .06
Sodium sulphite, crystals..... lb.	.03 - .04	.04 1/2 - .04 3/4
Strontium nitrate, powdered..... lb.	.12 - .12 1/2	.13 - .14
Sulphur chloride, red..... lb.	.05 - .05 1/2	.05 1/2 - .06 1/2
Sulphur, crude..... ton	20.00 - 22.00	
Sulphur dioxide, liquid, cylinders ex a..... lb.	.08 - .08 1/2	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.38 - .40
Zinc carbonate, precipitate..... lb.	.16 - .16 1/2	.17 - .17 1/2
Zinc chloride, gran..... lb.	.09 1/2 - .09 3/4	.10 - .11
Zinc cyanide..... lb.	.42 - .44	.45 - .47
Zinc dust..... lb.	.11 1/2 - .11 3/4	.11 1/2 - .12 1/2
Zinc oxide, XX..... lb.	.07 1/2 - .07 3/4	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.35 - .40
Aniline oil, drums extra..... lb.	.18 - .21
Aniline salts..... lb.	.25 - .28
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.00 - 1.25
Benzidine, base..... lb.	1.00 - 1.10
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.32 - .35
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.80
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .75
Cresylic acid, 95-97%, dark, in drums..... gal.	.60 - .65
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.20 - 1.25
Dimethylaniline..... lb.	.43 - .50
Dinitrobenzene..... lb.	.26 - .28
Dinitrochlorobenzene..... lb.	.20 - .30
Dinitronaphthalene..... lb.	.36 - .40
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.27 - .30
Dip oil, 25%, ear lots, in drums..... gal.	.40 - .45
Diphenylamine..... lb.	.65 - .70
H-acid..... lb.	1.15 - 1.25
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.75 - 1.85
Naphthalene crushed, in bbls..... lb.	.06 1/2 - .07 1/2
Naphthalene, flake..... lb.	.06 1/2 - .08
Naphthalene, balls..... lb.	.08 - .09 1/2
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3.10 - 3.20
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.80 - .85
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.60 - 1.75

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.75 - .80
Para-nitrotoluene..... lb.	.85 - .95
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums..... lb.	.08 1/2 - .10
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.60 - 1.65
Resorcinol, pure..... lb.	2.25 - 2.30
Salicylic acid, tech., in bbls..... lb.	.19 - .22
Salicylic acid, U. S. P..... lb.	.20 - .25
Salol..... lb.	.60 - .75
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulohanic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.25 - 1.35
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 -
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.50 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 - \$0.25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.36 - .42
Candelilla wax..... lb.	.25 - .26
Carnauba, Flora..... lb.	.48 - .50
Carnauba, No. 2, North Country..... lb.	.25 - .26
Carnauba, No. 3, North Country..... lb.	.14 1/2 - .15
Japan..... lb.	.24 - .25
Montan, crude..... lb.	.06 1/2 - .06 3/4
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 1/2 - .03 3/4
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 -
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03 1/2
Paraffine waxes, refined, 125 m.p..... lb.	.03 1/2 - .03 3/4
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 1/2 - .04 1/2
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 1/2 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 1/2 - .06
Stearic acid, single pressed..... lb.	.09 1/2 -
Stearic acid, double pressed..... lb.	.10 1/2 -
Stearic acid, triple pressed..... lb.	.11 - .11 1/2

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.25 - 5.30
Rosin E-I..... 280 lb.	5.30 - 5.40
Rosin K-N..... 280 lb.	5.55 - 5.70
Rosin W. G.-W. W..... 280 lb.	6.60 - 7.35
Wood rosin, bbl..... 280 lb.	6.25 -
Spirits of turpentine..... gal.	.68 -
Wood turpentine, steam dist..... gal.	.66 -
Wood turpentine, dest. dist..... gal.	.64 -
Pine tar pitch, bbl..... 200 lb.	 - 7.00
Tar, kila burned, bbl. (500 lb.)..... bbl.	 - 11.00
Retort tar, bbl..... 500 lb.	 - 11.00
Rosin oil, first run..... gal.	.35 -
Rosin oil, second run..... gal.	.37 -
Rosin oil, third run..... gal.	.44 -
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.90 -
Pine oil, pure, dest. dist..... gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 -
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 -
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 -
Pinewood creosote, ref..... gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 -
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 -
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 -
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 -

Crude Rubber

Para-Upriver fine..... lb.	\$0.16 - .17
Upriver coarse..... lb.	.09 - .09 1/2
Upriver caucho ball..... lb.	.11 1/2 - .12
Plantation—First latex crepe..... lb.	.14 -
Ribbed smoked sheets..... lb.	.12 - .12 1/2
Brown crepe, thin, clean..... lb.	.15 -
Amber crepe No. 1..... lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.09 1/2 - \$0.09 3/4
Castor oil, AA, in bbls..... lb.	.10 1/2 - .11
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.11 - .11 1/2
Cocanut oil, Ceylon grade, in bbls..... lb.	.10 - .10 1/2
Cocanut oil, Cochín grade, in bbls..... lb.	.10 1/2 - .11 1/2
Corn oil, crude, in bbls..... lb.	.08 1/2 - .08 3/4
Cottonseed oil, crude (f. o. b. mill)..... lb.	.08 - .08 1/2
Cottonseed oil, summer yellow..... lb.	.10 - .10 1/2
Cottonseed oil, winter yellow..... lb.	.10 1/2 - .11
Linseed oil, raw, ear lots (domestic)..... gal.	.73 - .74
Linseed oil, raw, tank cars (domestic)..... gal.	.67 - .68
Linseed oil, in 5-bbl lots (domestic)..... gal.	.75 - .76

Olive oil, Denatured.....	gal.	\$1.10	—	\$1.20
Palm, Lagos.....	lb.	.07	—	.08
Palm, Niger.....	lb.	.07	—	.07
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.08
Peanut oil, refined, in bbls.....	lb.	.10	—	.10
Rapeseed oil, refined in bbls.....	gal.	.86	—	.88
Rapeseed oil, blown, in bbls.....	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	.08
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.44	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.06	—	.07
Chalk, Precipitated, domestic, extra light.....	lb.	.04	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04
Chalk, Precipitated, domestic, heavy.....	lb.	.03	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04	—	.05
Chalk, Precipitated, English, light.....	lb.	.04	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	16.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.06	—	.07
Graphite, Ceylon chip.....	lb.	.04	—	.05
Graphite, high grade amorphous crude.....	lb.	.00	—	.02
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr f.o.b. N.Y.....	per ton	61.00	—	
Magnesite, calcined.....	per ton	66.00	—	70.00
Pumice stone, imported, lump.....	lb.	.03	—	.40
Pumice stone, domestic lump.....	lb.	.05	—	.05
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1 1/2 @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.52	—	.53
Shellac, orange superfine.....	lb.	.55	—	.56
Shellac, A. C. garnet.....	lb.	.44	—	.45
Shellac, T. N.....	lb.	.45	—	.46
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	10.00	—	14.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	40.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$37.50—40.00	
Carborundum refractory brick, 9-in.	1,000	1250.00	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	60	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30—32	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	33—35	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	36—40	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30—35	
Magnesite brick, 9-in. straight.....	net ton	70	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77	
Magnesite brick, soaps and splits.....	net ton	98	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	42—45	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	46—50	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35—38	

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00 — \$225.00	
Ferrochrome per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.12 —	
Ferrochrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.13 —	
Ferromanganese, 76-80% Mn, domestic.....	net ton	65.00 — 67.00	
Ferromanganese, 76-80% Mn, English.....	net ton	65.00 — 67.00	
Spiegelisen, 18-22% Mn.....	net ton	25.00 — 27.00	
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.50 —	
Ferrosilicon, 10-15%.....	net ton	38.00 — 40.00	
Ferrosilicon, 50%.....	net ton	60.00 — 65.00	
Ferrosilicon, 75%.....	net ton	130.00 — 135.00	
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.40 — .45	
Ferrouanium, 35-50% of U, per lb. of U content.....	lb.	6.00 —	
Ferrovanadium, 30-40% per lb. of contained V.....	lb.	4.25 — 4.50	

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Ilvaite, 52% Al content.....	net ton	\$8.00 — \$10.00	
Chrome ore, Calif concentrates, 50% min. Cr ₂ O ₃	unit	.27 — .30	
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	unit	.27 — .30	
Coke, foundry, f.o.b. ovens.....	net ton	4.25 — 4.50	
Coke, furnace, f.o.b. ovens.....	net ton	3.00 — 3.25	
Coke, petroleum, refinery, Atlantic seaboard.....	net ton	14.00 — 15.00	
Fluorspar, lump, f.o.b. mines, New Mexico.....	net ton	12.50 —

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GOODWATER—The Flake Graphite Corp. is planning for the rebuilding of its local plant destroyed by fire, Aug. 23, with loss estimated at close to \$500,000, including refining and other machinery.

California

LOS ANGELES—The Western Chemicals Co., 503 Merchants' National Bank Bldg., has plans under way for the construction of a new plant at San Pedro Harbor, comprising a main building, 40 x 200 ft., with wing extensions 40 x 100 ft. Headquarters of the company are at Tonah, Nev.

LONG BEACH—The Fredonia Window Glass Co., Fredonia, Kan., is considering the erection of a new glass-manufacturing plant on site selected at Long Beach. Plans are under way and construction will be commenced at an early date. The local Chamber of Commerce, George A. Brown, secretary, is interested in the project. C. F. Lutz is president and general manager of the company.

LONG BEACH—The Shell Oil Co. has completed plans for the construction of a number of new mechanical buildings at its plant in the Signal Hill section, to be located on Obispo Ave. The structures are estimated to cost \$51,000 and will comprise a machine works, 52 x 75 ft.; forge shop 52 x 60 ft.; mechanical shop and warehouse 76 x 90 ft., and other miscellaneous buildings.

Connecticut

NEW HAVEN—The Star Paper Co. will rebuild the portion of its plant, destroyed by fire Aug. 13, with loss reported at about \$12,000.

MANCHESTER—The Oxford Soap Co., Hilliard St., has filed plans for the construction of a 1-story addition to its plant, about 14 x 100 ft.

HARTFORD—The United States Envelope Co., 248 Pearl St., will commence the immediate erection of a new 4-story plant addition, estimated to cost about \$50,000. Contract for construction has recently been let to the Casper Ranger Construction Co., 20 Bond St., Holyoke, Mass.

Florida

PUNTA GORDA—The Southern Tanning & Mfg. Co., recently organized, is planning for the establishment of a local tannery for the production of high-grade leather products.

OCALA—The Sure Shot Timber Killer Co., recently organized to manufacture chemical products for the destruction of timber growths, weeds, etc., has plans under way for the establishment of a new local plant for the manufacture of its products. A local building has been leased for the works. E. H. Hopkins, Reddick, Fla., is president.

Georgia

BRUNSWICK—The Industrial Chemical & Fertilizer Co., recently incorporated, is planning for the construction of a new 1-story plant, 100 x 100 ft., to be equipped for the manufacture of fertilizer products. B. S. Brown is general manager.

Illinois

CHICAGO—E. F. Houghton & Co., 3524 Shields Ave., manufacturer of refined oil products, with main plant at Philadelphia, Pa., has filed plans for the construction of a new 1-story building, 30 x 100 ft., at its local works. The Austin Co., 208 South La Salle St., has the erection contract.

Louisiana

NEW ORLEANS—The Jefferson Distilling & Denaturing Co. is planning for the reconstruction of its local plant building, destroyed by fire Aug. 24, with loss estimated in excess of \$50,000, including equipment and stock.

NEW ORLEANS—The Colonial Chemical Corp., Reading, Pa., manufacturer of chemical compounds, disinfectants, etc., has leased a building at New Orleans for the establishment of a new branch works. George Bowman, secretary, will represent the company in this section.

Maryland

BALTIMORE—The Canton Co. has filed plans for the construction of a new plant on O'Donald St. near Third St. for the manufacture of lard and kindred products, consisting of a main 4-story building, 72 x 114 ft., and two 1-story structures, 50 x 58 ft., and 33 x 50 ft., respectively. The new plant will cost about \$75,000.

BALTIMORE—The American Sugar Refining Co. has filed plans for a 1-story building, 72 x 138 ft., at its new refinery, now in course of erection. The structure will be used for general manufacturing purposes, and will be located at Clement and Woodall Sts.

ARBUTUS—The Adamantex Brick Co. has construction under way on a new 2-story plant, 162 x 268 ft., to be equipped for the manufacture of sand-lime brick under a special process. The company has a tract of about 50 acres of property for its plant site and as a source of raw materials. The works will be equipped for a daily output of about 100,000 bricks, composed of sand, portland cement and a special chemical binder. Louis F. Drucker is president; and George B. Clemmert, 416 North Howard St., Baltimore, secretary and treasurer.

Michigan

HOLLAND—The DePree Chemical Co. has completed plans and will soon commence the erection of a new 2-story and basement building at its plant, 60 x 140 ft., estimated to cost about \$15,000.

Mississippi

GULFPORT—Charles T. Madison and George S. Dodds, Gulfport, are organizing a new company to construct an oil refinery on local site with daily output of about 300 bbl. of material.

Missouri

ST. LOUIS—The Standard Stamping Co., 2000 North Broadway, manufacturer of stamped metal products, has awarded a contract to the A. H. Haessler Contracting Co., Wainwright Bldg., for the erection of a new 1-story plant at Broadway and Madison St., 107 x 135 ft., to be equipped as an enameling works. George Weigand is president.

WACO—The American Zinc, Lead & Smelting Co., Pierce Bldg., St. Louis, Mo., has acquired the property of the High Five Mining Co. at Waco, for a consideration said to be \$250,000. The new owner plans to develop the site with installation of mining and other equipment.

KANSAS CITY—The Kelly Mill Co., Rochester and Park Aves., is reported to be planning for the rebuilding of its flour mill at location noted, recently destroyed by fire with loss reported in excess of \$250,000. A. B. Kelly is president.

Nebraska

ANTIOCH—The plant and equipment of the Alliance Potash Co. has been purchased by Herman J. Krause, who has been interested in the company, at a sheriff's sale, for a consideration said to be \$32,600. The plant was constructed about four years ago at a cost of close to \$500,000, including machinery. The new owner will reorganize the company and operate the works.

New Jersey

GLOUCESTER CITY—The Argo Paper Mills Corp. has been incorporated under Delaware laws with a capital of \$3,000,000, to operate a local plant for the manufacture of newsprint and other paper products. The company will take over the former Argo Mills plant at this place, previously used for the manufacture of textile products, and Frank J. Hummel, the owner of the property, heads the new organization. The works will be remodeled to accommodate

the new industry and equipment installed at an early date.

NEWARK—The Celluloid Co., 290 Ferry St., will take bids at once for the construction of a new 1-story building, 72 x 210 ft., located at Niagara and Westcott Sts., estimated to cost about \$200,000. The J. G. White Co., 43 Exchange Pl., New York, is architect and engineer.

New York

OGDENSBURG—The Bob White Chemical Co., formerly known as the Morgan Chemical Co., is planning for the construction of a new laboratory and other buildings at its plant.

CADYVILLE—The International Paper Co., 30 Broad St., New York, N. Y., has commenced the construction of a new hydro-electric power plant on the Saranac River, near Cadyville, estimated to cost about \$250,000. It will be used for paper mill operations in this district.

TROY—The Hercules Powder Co. is planning for the rebuilding of the portion of its plant at Schaghticoke, near Troy, recently destroyed by fire.

Ohio

ROSEVILLE—The T. S. Lowry Pottery Co. has completed plans for the erection of a new 1-story plant addition, 60 x 135 ft., estimated to cost about \$35,000. Construction will be commenced at an early date. N. I. Tyner is president.

DAYTON—The Allsteel Ridewell Tire & Rubber Co., 513 Lindsay Bldg., has completed plans for the erection of its proposed new plant on South Dayton St., to be 3-story and basement, 125 x 300 ft., and estimated to cost about \$500,000 with machinery.

YOUNGSTOWN—The Wells Process Co., Youngstown, is taking bids for the erection of a new plant at Conneaut, O., to be 1-story, 60 x 108 ft., and estimated to cost about \$25,000. Ralph Wells of the Wells Mfg. Co., Youngstown, heads the company.

Oklahoma

OKLAHOMA CITY—The Choate Oil Corp. is planning for enlargements in its oil refinery to increase the daily output from 2,500 to 3,000 bbl.

Pennsylvania

ECONOMY—The Wyckoff Drawn Steel Co., Frick Bldg., Pittsburgh, Pa., has completed plans for the erection of a 1-story addition to its plant at Economy, Pa., to be 60 x 240 ft.

PITTSBURGH—The Air Reduction Co., 120 Broadway, New York, has commissioned Architects Francisco & Jacobus, 511 Fifth Ave., New York, to prepare plans for its proposed new oxygen-manufacturing plant on property recently acquired on Ridge Ave., Pittsburgh, to be 1- and 2-story, 80 x 140 ft., and estimated to cost close to \$250,000 with equipment.

PHILADELPHIA—The General Smelting Co., Stock Exchange Bldg., has awarded a contract to H. E. Baton, 1713 Sansom St., for the erection of its proposed new 1-story plant at Bath and Westmoreland Sts., 60 x 100 ft., to be used for chemical service.

Tennessee

KNOXVILLE—The Pure Paint & Varnish Co., recently organized with a capital of \$150,000, has plans under way for the erection of a new 3-story plant on local site for the manufacture of paint, varnish and kindred products. It is estimated to cost about \$40,000. J. C. Trewitt, Knoxville, is vice-president in charge. J. R. Lee, Sparta, Tenn., is president.

CHATTANOOGA—The plant of the New Citico Brick Co. has been acquired by H. G. Fleming, J. J. Wall and associates. The new owners are planning for the erection of an addition to double the present output, approximating 40,000 bricks a day.

Texas

WANAHAHACHIE—The new oil refinery to be constructed by the Texas Oil Products Co., initial work for which is under way, will comprise the second unit of the company's local plant. The first unit is now in operation under a 24-hour period, with output rated at 500 bbl. per day. The new extension will have a like capacity.

WILLS POINT—The Van Zandt Cotton Oil Co., recently incorporated with a capital of \$600,000, is planning for the erection of a local plant for the manufacture of cottonseed oil and byproducts. W. P. Allen heads the company.

New Companies

THE ANSONIA CHEMICAL Co., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are W. S. Perry, F. S. Mordaunt and L. Sterns. The company is represented by DeWitt & Mulqueen, 111 Broadway.

THE CARBOLOID PRODUCTS CORP., Jersey City, N. J., has been incorporated with a capital of \$20,000, to manufacture composition specialties. The incorporators are William E. Barddusch, Emil W. A. Schumann and William H. Carey, 1 Montgomery St.

THE BECKER PAPER Co., Springfield, Mass., has been incorporated with a capital of \$50,000, to manufacture paper goods. Earl Becker, Springfield, is president and Edward M. Miller, treasurer.

THE MYSTIC GLASS Co., Los Angeles, Cal., has been incorporated with a capital of \$300,000, to manufacture glass products. The incorporators are John V. Hoffman, LeVerne Fox and George D. Hussey. The company is represented by David P. Hatch, Room 1121 I. N. Van Nuys Bldg.

THE FIBROUS MFG. Co., 130 Market St., Newark, N. J., has filed notice of organization to manufacture fiber products. The company is represented by Elwood B. Hendricks, 645 Springdale Ave., East Orange, N. J.

THE CALUMET CHEMICAL Co., 4100 Fillmore St., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are F. O. Mason, P. Lee and Raymond S. Pruitt.

THE MCRAE STEEL Co., Detroit, Mich., has been incorporated with a capital of \$30,000, to manufacture steel products. The incorporators are Herbert C. Shotwell, D. Shepard Shine, Jr., and Kenneth C. McRae, 2714 Pingree Ave.

THE DEFIANCE PAINT PRODUCTS Co., INC., South River, N. J., has been incorporated with a capital of \$500,000, to manufacture paints, varnishes and kindred products. The incorporators are Benjamin W. Moreland, John H. Sloan and Matthew H. Loughridge, South River.

THE RIDDLE MFG. Co., Jacksonville, Fla., has been incorporated with a capital of \$25,000, to manufacture chemicals, and chemical byproducts. J. R. Crosby is president; W. H. McGee, vice-president; and G. B. McDaniel, secretary-treasurer, all of Jacksonville.

THE FRENCH QUALITY TOILET SOAP MFG. Co., Brooklyn, N. Y., has been incorporated with a capital of \$40,000, to manufacture soaps and affiliated products. The incorporators are G. R. Hall, M. L. Gilman and C. Steiner. The company is represented by C. S. Sachs, 119 Nassau St., New York.

THE DUSTBANE PRODUCTS Co., 3629 South Ashland Ave., Chicago, Ill., has been incorporated with a nominal capital of \$5,000, to manufacture sweeping compounds and other chemical products. The incorporators are M. B. Woodrich, Daniel Burkhartsmeier and G. A. Gillmurry.

THE GOLDEN STATE COLOR & CHEMICAL WORKS, Obispo Ave., Long Beach, Cal., has filed notice of organization to manufacture chemicals and affiliated products. James V. Nevin, 2817 East Second St., Long Beach, heads the company.

THE METAL GOODS MFG. Co., Boston, Mass., has been incorporated with a capital of \$100,000, to manufacture metal products. Ralph C. Heath, 267 Washington St., Melrose, Mass., is president and treasurer.

THE GORTON PAPER CORP., Bridgeport, Conn., has been incorporated with a capital of \$50,000, to manufacture paper goods. The incorporators are C. W. Gorton, N. P. Bump and C. T. Appleton, 45 Curtis Ave.

THE PENN SHOPE BRICK Co., Reading, Pa., has been incorporated with a capital of \$50,000, to manufacture brick and other burned clay products. A. F. Kostenbader, Reading, is treasurer.

THE STELLAR CHEMICAL Co., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemicals and chemical byproducts. The incorporators are H. S. Leman, A. M. Lee and H. M. Schechter. The company is represented by H. N. Wessel, 45 Cedar St.

THE SANDY CREEK OIL Co., Port Arthur, Tex., has been incorporated with a capital of \$100,000, to manufacture petroleum products. The incorporators are A. V. McFadden and F. C. Pfeiffer, Port Arthur.

THE JORDON SPECIALTY Co., Tampa, Fla., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. Leo B. Jordon is

president; A. T. Jordon, vice-president; and P. T. Jordon, secretary and treasurer, all of Tampa.

THE RELIABLE JAPANING Co., INC., Newark, N. J., has been incorporated with a capital of \$25,000, to manufacture japanned metal goods, electroplated wares, etc. The incorporators are Frank Principe, Peter and Walter F. Lynch, 14 Ferdon St.

THE ROTARY OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$200,000, to manufacture petroleum products. The incorporators are James M. Ross, William H. Yerian and W. G. Purser. The company is represented by Peyton H. Moore, 915 Black Bldg.

THE CLARK PAPER TUBE Co., Huntington, W. Va., has been incorporated with a capital of \$50,000, to manufacture paper products. The incorporators are George G. Clark and G. F. Templeman, Huntington.

THE MIDDLESEX OIL CORP., Perth Amboy, N. J., has been incorporated with a capital of \$125,000, to manufacture refined oil products. The incorporators are Samuel Sedersky and Oliver H. Brown. The company is represented by Joseph E. Stricker, 117 Smith St.

THE CONSOLIDATED OIL PRODUCERS, INC., Los Angeles, Cal., has been incorporated with a capital of \$1,500,000, to manufacture petroleum products. The incorporators are T. S. Trebell, Harvey A. Young and Irving V. Auger. The company is represented by James E. Kelby, 929 W. P. Story Bldg.

THE STANDARD STEEL Co., Detroit, Mich., has been incorporated with a capital of \$10,000, to manufacture steel products. The incorporators are Julius G. and Samuel B. Solomon, 220 Elmhurst Ave., Highland Park, Detroit.

THE J. & M. BRICK Co., 903 Boundry Ave., Los Angeles, Cal., has filed notice of organization to manufacture brick and other burned clay products. The company is headed by D. B. Jeffries, 1818 West 49th St.

THE RUBBER SERVICE Co., South River, N. J., has been incorporated with a capital of \$50,000, to manufacture rubber goods. The incorporators are Anders K. White, Chester R. Holman and Herman W. Ritter, South River.

THE GIBSON OIL Co., Vincennes, Ind., has been incorporated with a capital of \$250,000, to manufacture petroleum products. The incorporators are A. W. Keith, J. M. England and W. F. Farrell, Vincennes.

THE NEW YORK PAINT REMOVER & MOTOR CLEANING Co., INC., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemical specialties, cleaning compounds, etc. The principal incorporator is W. A. Craddock, 10 West 61st St.

THE MARSHALL-PRESTON OIL PRODUCING & MFG. Co., Cameron, W. Va., has been incorporated with a capital of \$50,000, to manufacture petroleum products. The incorporators are C. E. Plummer and G. T. Logsdon, Newburg, W. Va.

JAMES A. ROSS, INC., Boston, Mass., has been incorporated with a capital of \$100,000, to manufacture chemicals and affiliated products. James A. Ross, 1 Canal St., Lawrence, Mass., is president and treasurer.

THE WHITE STAR OIL Co., Monroe, La., has been incorporated with a capital of \$100,000, to manufacture refined oil products. Henry Burnstein is president; Allan Sholars, vice-president; and John J. Potts, secretary and treasurer, all of Monroe.

THE OKLAHOMA LUBRICATING OIL Co., Oklahoma City, Okla., has been incorporated under Delaware laws, with capital of \$400,000, to manufacture lubricating and other refined oils. The company is represented by the Corporation Trust Co., of America, Du Pont Bldg., Wilmington, Del.

THE PENLAND FELDSPAR & KAOLIN Co., Penland, N. C., has been incorporated with a capital of \$25,000, to operate feldspar and clay properties. The incorporators are Charles R. Harry and L. P. Bailey, all of Penland, N. C.

HENCHY & FITZSIMMONS, INC., New York, N. Y., has been incorporated with a capital of \$15,000, to manufacture chemical specialties. The incorporators are R. F. Henry, J. J. Flood and G. F. Maguire, 149 Broadway.

THE TRIANGLE CHEMICAL Co. has been organized in Vancouver, B. C., to manufacture hydrochloric acid, sulphuric acid, superphosphates, and fertilizers generally. The company has arranged with the city of New Westminster for a lease of land on the waterfront of the Northwest arm, where a plant is to be erected.

THE SHRIVER OIL Co., Westminster, Md., has been incorporated with a capital of

\$50,000, to manufacture refined oil products. The incorporators are Robert T. R. S. and William H. Shriver, Westminster.

THE CARONI PRODUCTS Co., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture flavoring extracts, alcohol byproducts, etc. The incorporators are H. J. Terwilliger, E. R. Whittingham and W. C. Blach. The company is represented by Stockton & Stockton, 2 Rector St., New York.

THE PACIFIC MINERALS & CHEMICAL Co., INC., New York, N. Y., has been incorporated under Delaware laws, with a capital of \$10,000,000, to manufacture chemicals, chemical byproducts and kindred specialties. The company is represented by Arthur W. Briton, 65 Cedar St.

THE OHIO-KENTUCKY FLUORSPAR & LEAD CORP., Smithland, Ky., has been incorporated with a capital of \$1,000,000, to operate fluorspar and lead properties, lead refining plants, etc. The incorporators are F. B. Moddle, Smithland; and Thomas J. Clay, White Castle, La.

Capital Increases, Etc.

THE OWEGO MFG. Co., Owego, N. Y., has been merged with the Wilbur White Chemical Co., Owego, under the latter name.

THE APONA CHEMICAL Co., South Bend, Ind., has filed notice of dissolution under state laws.

THE KLEYENSTEUBER-WHITE FOUNDRY Co., Birmingham, Ala., manufacturer of metal castings, has increased its capital to \$20,000. M. G. Kleyensteuber is president.

THE NEW JERSEY CAR SPRING & RUBBER Co., 91 Brunswick St., Jersey City, N. J., has filed a petition in bankruptcy. The assets and liabilities have not been stated.

THE WOLVERINE PETROLEUM Co., Saginaw, Mich., has filed notice of increase in capital from \$50,000 to \$250,000.

THE GLIDDEN Co., Cleveland, O., manufacturer of paints, varnishes, etc., has arranged for a bond issue of \$3,350,000. Adrian D. Joyce is president.

THE CORSICANA PETROLEUM Co., Houston, Tex., has filed notice of increase in capital from \$20,000 to \$80,000. J. H. Farber is president.

THE LAWTON REFINING Co., Lawton, Okla., manufacturer of refined petroleum products, has filed notice of increase in capital from \$100,000 to \$150,000.

THE LIMETON LIME Co., Front Royal, Va., manufacturer of lime products, has filed notice of increase in capital from \$20,000 to \$50,000. R. E. Herr is president.

THE SALT SPRINGS SOLAR COARSE SALT Co., Syracuse, N. Y., has filed notice of reduction in capital from \$120,000 to \$24,000.

Manufacturers' Catalogs

THE CONVEYORS CORPORATION OF AMERICA, Chicago, Ill., has issued a booklet, "The Proof of the Pudding," which consists of 70 testimonial letters received from users of its conveyors. Copies will be sent on application.

THE YALE & TOWNE MFG. Co., Stamford, Conn., has issued two leaflets. The first is on "Electric Industrial Trucks, Model A-17 Crane Truck" and the second on "Electric Industrial Trucks, Model C-6-36 Trailer." Illustrations and specifications are given.

THE YORK MFG. Co., York, Pa., calls attention to Bulletin 10a, which supersedes Bull. 10, on ice-making and refrigerating machinery.

THE ATLAS VALVE Co., Newark, N. J., calls attention to Bulletin 5, entitled "Victor Damper Regulator No. 3, High Pressure." This regulator is designed for boiler pressures up to 250 lb.

THE NASH ENGINEERING Co., South Norwalk, Conn., has published a catalog covering Jennings hytor return line vacuum and low pressure boiler feed pumps. This is known as Bulletin 15.

THE INGERSOLL-RAND Co., New York, has issued a very attractive catalog on its products. This catalog gives a general idea of the numerous products manufactured by the company. For easy reference the products have been subdivided into various classifications. Particular attention is called to the Engineering Data Section, which is of value in solving everyday pneumatic problems, and in determining exact requirements for new equipment.

Industrial Notes

THE ENGINEERING ADVERTISERS' ASSOCIATION, Chicago, has proposed, and the Technical Publicity Association of New York has seconded, the proposal to hold an industrial advertising conference with the Associated Advertising Clubs of the World, meeting in Milwaukee in 1922. Both the Chicago and New York advertising associations have a large membership representing industrial and technical advertisers. The rapid growth of this kind of advertising and the necessity for specialist treatment in its development make it necessary to consider the subject apart from the usual question pertaining to advertising, and accordingly a special program for industrial advertising is proposed for the Milwaukee convention. The conference will serve an important purpose in suggesting new subjects for thought and investigation by advertising agencies.

THE GASOLINE RECOVERY CORP., New York, announces that a commercial natural gas gasoline plant operating according to the Burrell-Oberfell charcoal process is in operation at Bradford, Pa. The plant has a capacity of 900 gal. per day. It is also announced that the charcoal gasoline plant of the Monroe-Louisiana Carbon Co., located at Monroe, La., is nearing completion.

THE SCHAFFER ENGINEERING & EQUIPMENT CO., Pittsburgh, Pa., announces the combining of the administrative, sales and manufacturing departments in its new general offices at 2828 Smallman St., Pittsburgh, Pa.

THE COCHRANE STEAM SPECIALTY CO. OF MASSACHUSETTS has been organized to represent in New England a number of well-known manufacturers of power-plant equipment, including the H. S. B. W.-Cochrane Corp., manufacturer of feed water heaters, steam and oil separators, V-notch meters and metering heaters, hot and cold process softeners, flow meters, precision meters, weighing meters, multiport valves and multiport drainers, also the Steam Motors Co., Inc., manufacturer of steam turbines for driving generators, pumps, fans, etc., and the D. Connelly Boiler Co., builder of water tube steam boilers. The office at 1045 Oliver Bldg., Boston, Mass., is in charge of Elliott Greene.

THE LINK-BELT CO., Chicago, has acquired all of the capital stock of the H. W. Caldwell & Son Co., and Frank C. Caldwell has been elected a director of the Link-Belt Co. The H. W. Caldwell & Son Co.'s plant will continue to operate under separate corporate existence under its present name.

THE SULLIVAN MACHINERY CO., Chicago, Ill., has moved its Cleveland office from 810 Park Bldg., to Room 824, Kirby Bldg. Ralph T. Stone is manager. It is also announced that a supply depot and service station for coal-mining machinery supplies and repair parts has been opened at Seventh Avenue and Thirteenth Street, Terre Haute, Ind. H. T. Wiley is in charge.

CHARLES CORY & SON, INC., 183-187 Varick St., New York City, has obtained the manufacturing and selling rights for the Royer line of portable and stationary flow indicators. These indicators are designed for indicating the flow of all kinds of corrosive and non-corrosive gases, vapors and liquids and were formerly manufactured and sold by the A. H. Sloan Co. of Detroit, Mich. It is intended, through the increased manufacturing facilities provided by the Cory company, to increase the production of these meters and make further extensions to the Royer line.

THE MALCOLMSON ENGINEERING CO. has just finished the peat harvesting machinery for the Dominion Government Peat Committee at Alfred, Ont. This involves equipment for excavating the peat from the ground and distributing it in piles for air-drying, when it is later picked up ready for the market.

THE MALCOLMSON ENGINEERING & MACHINE CORP., Old Colony Bldg., Chicago, Ill., has just completed the plant of the Tennessee-Illinois Phosphate Co., at Centerville, Tenn.

CASE SERVICE, INC., District National Bank Bldg., Washington, D. C., is an organization conducted for the purpose of serving non-residents of Washington, who have relations with various branches of the Government. It is designed to expedite business through personal attention.

C. W. LEAVITT & Co., New York, have been appointed selling agents in the United States for Mines de Manganese, Marquesa-Baja, Chile, producer of high-grade manganese ore. New equipment now being installed at the mines will place that company in a position to ship up to 300,000 tons manganese ore per annum.

New Publications

BOOKS

TECHNOLOGY OF CELLULOSE ESTERS, VOL. I, in five parts. By *Edward Chauncey Worden, First*. Pp. 3,709; 296 illustrations. New York: D. Van Nostrand Co., 1921. Price, \$40.

Those interested in the subject of nitrocellulose and other cellulose esters are familiar with the author's earlier two-volume "Nitrocellulose Industry" and with Vol. VIII of this series on cellulose esters, which deals with cellulose acetate. The volume just issued represents the combined efforts of a number of workers over a period of years. Some idea of the labor involved may be gained from the fact that there are 19,611 footnotes covering 39,458 patent and 80,504 literature references to the work of 33,740 investigators. Part 1 treats the raw materials cellulose, starch, cotton and the preparation of cotton for esterification; part 2, nitric acid, sulphuric acid and mixed acids; part 3, nitrocellulose theory, nitration of cellulose, analytical determinations of the cellulose nitrates; part 4, historical development of the cellulose esters. Part 5 is the patent, name and subject index to the first four parts.

TRANSACTIONS OF THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, Vol. XIII, Part I, 1920. Pp. 463, illustrated. New York: D. Van Nostrand Co., 1921. Price, \$6.

This volume contains the papers presented at the Montreal meeting, June, 1920.

A DICTIONARY OF APPLIED CHEMISTRY, Vol. II, revised and enlarged edition. By *Sir Edward Thorpe*, assisted by eminent contributors. Pp. 717, illustrated. London and New York: Longmans, Green & Co., 1921. Price, \$20.

This volume of the revised and enlarged edition covers topics from calculus to explosion, gaseous. Some of the more important articles are as follows: Camphor, Candles, Carbohydrates, Carbon, Cellulose, Cement, Chemical Affinity, Chlorine, Chromium, Cinchona Alkaloids, Citric Acids, Clay, Cobalt, Coke Manufacture and the Recovery of Byproducts, Colloids, Colorimeters, Color and Chemical Constitution, Copper, Corrosion of Metals, Corrosion (Protection of Metals From), Corrosion and Fouling of Steel and Iron Ships and Its Prevention, Creosote, Cyanides, Decolorising Carbons, Desiccation and Drying, Diazo-Compounds, Disinfectants, Distillation, Dyeing, Dyestuffs (Identification on Fabrics), Electrodeposition and Electroplating, Esterification, Ethyl, Evaporation, Explosion (Gaseous).

AMERICAN SULPHURIC ACID PRACTICE. By *Philip DeWolf* and *E. L. Larison*. Pp. 270; 85 illustrations. New York: McGraw-Hill Book Co., Inc., 1921. Price, \$3.50.

This is the first book to deal with modern American sulphuric acid practice from the point of view of actual plant operation. It is designed to meet the needs of, say, a new chamber operator or of men in allied lines who wish to acquaint themselves quickly with the subject. After introductory chapters on the history of the industry, elementary chemistry of H_2SO_4 , characteristics and uses, the raw materials and the production of SO_2 are discussed. The chamber process is treated in the following chapters: A brief description of the process, dust-settling apparatus, the Glover tower, the chambers, Gay-Lussac towers, acid circulation, introduction of niter, draft, testing, operation, concentration. An outline of the contact process is followed by chapters on purification of gases, converting, absorption, and converter mass. A special chapter on accounting was prepared by W. M. Le Clear. Acid tables, data for calculating the volume of acid in tank cars, etc., are given in the appendix.

THE ELECTRIC FURNACE. By *J. N. Pring, D.Sc.* Pp. 485; 241 illustrations. London and New York: Longmans, Green & Co., 1921. Price, \$10.50.

Practically all electrochemical and electrometallurgical process in which the electric current functions as a source of heat energy are included in this book, which is one of the monographs on industrial chemistry edited by Sir Edward Thorpe. Electrolysis in aqueous solutions is outside the scope of the text, although the electrodeposition of zinc and copper is referred to briefly. The electrochemical industries include calcium carbide, nitrogen fixation and ammonia oxidation, carborundum, aluminum, graphite, phosphorus, carbon bisulphide, electrolytic processes with fused electrolytes (aluminum, sodium and calcium). The electrometallurgical industries are the electric smelting of iron ores, electric steel, ferro-alloys, melting and prepara-

tion of non-ferrous metals and alloys, electric smelting of zinc, copper and tin ores. There are also general chapters on the principles of electric furnaces, laboratory and experimental types, current supply, transformers, pyrometry, refractories, heat losses through walls and electrodes, design of terminals, power expenditure, water-power developments, steam-power stations and electrochemical centers. In short, electric furnaces and their industrial applications are very thoroughly covered.

CERAMICS. By *A. Malinovsky*. Pp. 274, illustrated. New York: D. Van Nostrand Co., 1921. Price, \$3.

A condensed review of ceramic processes, including the methods of qualitative and quantitative analysis of silicates, and chemical and ceramic calculations used in everyday practice. Many tables which will be helpful to the ceramic engineer are also included.

METALLURGY OF THE COMMON METALS. Fifth edition. By *Leonard S. Austin*, formerly professor of metallurgy and ore dressing, Michigan College of Mines. Pp. 615; 330 illustrations. New York: John Wiley & Sons, Inc., 1921. Price, \$7.

Since 1913, the date of the last edition, such radical changes and improvements have been made in the metallurgy of the common metals that this edition has been largely rewritten. Great pains have been taken to set forth underlying principles clearly and at the same time to give the details of methods and metallurgical equipment, and their cost. A chapter has been devoted to questions of the economic situation of the business of metallurgy. Little attempt has been made to describe methods not now in use.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS is holding its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) is being held this week in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del., Oct. 18 to 20.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Sixty-second Meeting of The American Chemical Society

THE sixty-second meeting of the American Chemical Society is over, and it may be described as a good one. Under the distinguished presidency of Dr. EDGAR FAHS SMITH it was bound to have quality. The man at the head is certain to give tone to what he directs, and the Provost Emeritus is of the Blood Royal of Good Fellowship. It could not be a commonplace meeting, although it bore none of the hallelujah appellations so dear to the hearts of the scare-head writers. It did not suffer from being a "Get Together" or a "Press Onward" meeting. It was just the sixty-second meeting, and excellent of its kind.

There were 334 papers presented before the various divisions, and that was, of course, too many. One can get "fed up" on almost any subject, and we are of the opinion that fewer papers and livelier discussions would do more to speed the gospel of chemistry and the enlightenment that goes with it than more papers and less talk. Perhaps if, after every fifty minutes, a recess of ten minutes were taken it would give those present a chance to stretch their legs and get a breath of fresh air. After several hours of miscellaneous listening one gets tired and classroom-worn. He misses points, and if he is tired enough he will agree tentatively by saying nothing when his chemical conscience should have prompted him to protest, or to oppose that with which he does not agree.

The international meeting in the Great Hall of the City College was an occasion of leading importance, and the papers were full of meat. But this also was too long. To listen to papers, even of such rare merit as these, from 2:30 until after 5 o'clock is too much. It was like a Gothic festival: so bounteous as to paralyze.

On the whole the meeting was an important scientific achievement. Our only criticism is a call for reorganization of the method of presenting papers. We think a little closer association of division chairmen might bring about a correction of this weariness factor. As the meetings are now conducted the incidence of weariness is too early; it comes long before the sessions are over.

Is It Dyes, Dyers, Ignorance or Cupidity?

ON THE afternoon of September 13 there was called an informal meeting in the clubrooms of the United Waist League of America, to discuss problems and troubles relating to dyes and dyed goods. Curiously enough—for such is the mutability of space!—this association of manufacturers of ladies' ready-made waists occupies the former habitation of the learned Grolier Club, and in the very apartment where the discussion took place there were erstwhile disputes as to first editions of Junius, exhibitions of renaissance bindings,

second folios of Shakespeare, and, if we remember aright, it was there that we saw for the first time a Breeches Bible. Who dares deny that time is a dimension of space?

On September 13, however, the discussion was far more direct and to the point than is the habit of bibliophiles in their arguments. Manufacturers of garments are having trouble with dyed goods today, and some complained that the quality was worse than ever before. One of the principal complaints was of black silks and navy blues. Another frequent trouble was with "bisque," a light shade of tan. Others reported difficulty in getting desired results in woolen goods. If producers of cotton goods were present, they were less audible than the others. Mr. MOESSOHN, the chairman, explained the difficulty: they buy the materials, make them up into garments, and then complaints come in. Thereupon they endeavor to trace the source of trouble, and there follows a manifestation of "passing the buck" that leaves the garment manufacturer bewildered and no wiser than he was before. He doesn't get anywhere when he tries to find out.

The desire was generally expressed, except by a few silent representatives of importers of German dyes, that the American dye industry be maintained, and the statement was made that the fault does not lie in American-made products. It was soon made clear that black silks, for instance, should be dyed with logwood, and that there is no shortage of that material nor any novelty in applying it. The delicate, light shades, it was declared, never had been fast, and against this was reported a claim by one establishment that it had developed a new process that makes "bisque," for instance, reasonably fast to light and wash—if the water is not too hot.

A complaint about blue bathing suits brought out the fact that the goods had been dyed with a perfectly good color—for other purposes—but that the medium used was not and never had been fast to light, salt water and perspiration.

This brought out the fact that very often the dyer does not know what the goods are to be used for. Fastness is a relative term. No dye ever was or ever will be absolutely fast. Yarn for bathing suits requires different dyes and treatment from yarn for dress goods. Black stockings—at least in the good old days when we were young—did not have to be made fast to light.

A gentleman of large experience said that in the past eight or nine years a large number of so-called dyers had sprung up in this country who are not dyers at all; they are painters.

Mr. BLUM of the United Piece Dye Works, who speaks with unquestioned authority, said that 90 per cent of the dyes we had before the war are made here, and the remaining 10 per cent can be obtained under license. The fault, he said, does not lie with the American-made products. Every trouble in dyeing has its specific

cause, and the number of them is legion. We are likely to forget that 1914 was nearly eight years ago, and that many classes of goods were as unreliable then as they are now. Mr. LEE, of the National Vigilance Committee, said that, what with high prices and buyers' strikes, the public had a grouch, and was disposed to blame the profiteer if anything was wrong. Dr. MATTHEWS, of the *Color Trade Journal*, struck the keynote when he said that goods should be dyed for quality rather than for price.

The meeting concluded with the appointment of a strong committee of textile chemists, dyers and manufacturers of garments to take up each complaint, trace each piece of goods through its history and find out what is wrong. That will bring out the fault and indicate just where it lies. It will show up incompetent dyers and put the blame on the man who skimmed his work, no matter who he be, and whether the cause were due to the strain of economy, ignorance of conditions that should have been understood, lack of right dye or use of wrong one, or downright incapacity.

We have nothing to take back of what we said lately about the trouble with dyed goods.

Further Defense of The Selective Embargo

ONE of the arguments sometimes urged against the selective embargo feature of the dye bill is that it is a legislative experiment and entirely revolutionary in nature. In answer to these objections most of us have been content to emphasize the fact that the unusual character of the present emergency and the vital importance of the dye industry call for a new and unusual sort of legislative treatment. We have felt, however, that this answer was not always convincing and we are very grateful, therefore, to the good friend who has called to mind a rather striking parallel of the dye bill. Think back for a moment to the recent immigration law. Is it not of exactly the same nature as the selective embargo? American labor found itself out of employment and the few existing jobs were threatened by an influx of cheap labor from abroad. Foreign countries were preparing to dump their surplus population on this country. Did we permit them to do it? No; the zealous safeguards of labor were on the job and quickly devised a careful plan for the restrictive control of immigration. At first we were frankly skeptical of the measure and not altogether sure that it was right in principle, but we are ready to admit that as far as our observation goes the embargo on immigration has contributed much to the common good.

Certainly the case of the dye industry has been so carefully and completely presented that it is scarcely necessary for us to vouch for the validity of its claims. The heads of our military establishments have told us that a dye industry is not only a helpful adjunct in the prosecution of modern warfare but is absolutely essential to the national defense. Economists have shown it to be a key industry upon whose products the employment of millions is dependent. The medical fraternity relies upon it for the medicinals vital to our health and happiness, and finally our universities and colleges—in fact the science of chemistry itself—cannot progress if this industry is stifled. When so much is at stake, why should we hesitate? The welfare of the nation will be served by the selective embargo on dyes, and certainly it is no more revolutionary than much of our present law.

A number of similar precedents can be found even in the existing tariff schedules. The Department of Agriculture, for example, can place an absolute embargo on foods which fail to meet the standards of the pure food and drugs act. Potatoes, grain, farm animals, pets, foreign drugs, vaccines and serums and many other articles can be imported only under strictest quarantine which in many cases amounts to a practical embargo. Are these commodities more inimical to the good of the country than are the products purposely intended to destroy our dye industry? We think not.

Mr. Ford's Offer For Muscle Shoals

LOOKING backward into the history of the notorious Muscle Shoals project, the fact stands out that there has been a deliberate confusing of the public mind in connecting the manufacture of nitrates with water-power development on the Tennessee River. Private interests desiring to enrich themselves at the expense of the Federal Government and politicians seeking forced economic development in one small section have been largely responsible for this.

Supported by President WILSON, Senator UNDERWOOD succeeded in locating the nitrate plants in Alabama, not because it was the best place to get them finished quickly for the nation's defense in time of war but rather for the reason that the South would be benefited. So one need not be surprised to find in Mr. FORD'S recent offer to lease the water power and purchase the nitrate plants the same attempt to handle the two things in lump bargaining. They should be considered separately, because the factors affecting each are entirely different.

As a matter of fact not one kilowatt of power from the Tennessee River was ever used, nor need it ever be required to operate these establishments at full capacity. Both U. S. Nitrate Plant No. 1 and No. 2 have fully equipped steam power houses on the properties and are connected in a common system with the Alabama Power Co. network and the Government power plant at Gorgas, on the Warrior River.

Water-power development at Muscle Shoals, promoted in Congress on the plea of war-time emergency by the local interests and put through by President WILSON for political reasons, has always been a questionable business venture in the minds of engineers and economists. However, the first dam stands partly constructed with about \$17,000,000 expended in a territory where power cannot now be sold. It is estimated that approximately \$31,000,000 more must be spent to complete the entire project. Mr. FORD would have the Government expend this latter sum and he would in turn attempt to establish industrial enterprises to use the power. He would have it further grant him special rights, contrary to existing policies built up after fifteen years struggle for conservation of water power.

The Roosevelt policy, now a law, provides that water-power leases shall be limited to fifty years with possibility of recapture by the Government at the end of that time; provides for regulation of price to power consumer, and that public water power taken for profit shall make a return to the public. Mr. FORD wants a lease for 100 years with indefinite renewals at the end of that time, or, in other words, continued private possession. His offer provides for no check on what the power consumer must pay. Further, he would receive several hundred thousand horsepower for nothing.

Consistent action on the Government's part would be to make a deal with Mr. FORD or other interested parties, whereby the existing works on the Wilson dam be purchased and a standard contract be entered upon for continued development and use of power on the same basis as at any other water-power site. The partly completed dam can much more economically be liquidated at a discount on \$17,000,000 than for the Government to spend \$31,000,000 more in times when money is sorely needed in other departments. Liquidation of the minor sum rather than added appropriations of the larger sum for construction is certainly a business-like procedure at this time.

Mr. FORD then asks that the two nitrate plants, Waco quarry, Gorgas power plant and an 80-mile transmission line be thrown in as a sort of horse trade for only \$5,000,000. Now, these are first-class properties which cost close to \$100,000,000 and are not to be compared with temporary war plants like Nitro, W. Va. Writing off the excessive cost due to war times, it would cost about \$50,000,000 to replace them today.

It would be necessary for the purchaser to convert Plant No. 1, costing \$13,000,000, to other uses, for the process was unsuccessful at this location. However, the cost of the apparatus which would necessarily be scrapped is a small proportion of the value of the plant.

Plant No. 2 is a valuable chemical property, probably the largest in the world. It can be operated to produce several basic chemicals and fertilizers and at the same time be held intact for military emergency. There is nothing particularly mysterious or out of the ordinary about the apparatus. One 60,000-kw. power house, one process steam plant, twelve 8,500-kva. carbide furnaces, seven rotary limekilns, coal-pulverizing plant, two 600-ton mills, thirty-six nitric acid towers, 1,532 electric ovens, twenty-three 600-lb. air compressors, fifty-six autoclaves, filtering and causticizing plant, 696 catalyzers are some of the items, all usable equipment to chemical engineers. Numerous large permanent plant buildings and several hundred permanent homes are located on a tract of about 1,700 acres of land.

It is not necessary to accept Mr. FORD's offer because it is the only one made at this time. Other companies in the chemical manufacturing business would doubtless pay considerably more for the property listed above were it not for the present financial depression. They simply cannot in sound business policy entertain expansion when their own plants are running at low capacity. In the meantime the Government can afford to wait, for cash maintenance in standby condition costs only the time of a few officers, a score of men and a negligible amount of material.

Mr. FORD shows he is a good business man, because he has conserved his cash resources to purchase when things are cheap. Maybe he could manufacture fertilizer at No. 2 so cheaply that a flivver would be found in each 2,000-lb. package. We also recall that he was going to "call the boys out of the trenches by Christmas," or, in other words, a pacifist is proposing to take over a property that may be needed in war. This situation might involve delay at a moment embarrassing to the nation. His business ability is a thing of passive interest to the private citizens, but all are actively concerned that those in command of these affairs should likewise display sufficient acumen to realize that this is not the time to throw valuable property on the market to the highest bidder. The Government can afford to wait for a better market.

Railroad Service

And Railroad Buying

SOME ideas die hard, and one of these is the idea that the railroads of the United States can contribute largely to the prosperity of the country by making purchases. With many of those who are talking of prospective railroad buying, self-interest is prominent. What they want is orders. The history of American railroading can be divided into three periods. The first was a period in which railroading was exploited by speculators. The second was one in which railroads were thought to exist chiefly for the purpose of placing orders. The third period was one in which a large number of persons thought the chief function of the railroads was that of having payrolls. In the hope of making that period permanent the "Plumb plan" was devised. The railroad payrolls are now undergoing a slow process of deflation, by reducing the number of names and the quantity of emolument per name. Let us hope that a fourth period will be inaugurated in which the universal view will be that of the railroads existing chiefly for the purpose of rendering service to the public.

The idea still prevails in some quarters that normal or at least accumulated requirements of the railroads can furnish employment to a large proportion of the steel-producing industry. That is not the case now. It was the case occasionally years ago, when there were great bursts in railroad building and the iron and steel industry was very much smaller than it is now. To illustrate, more miles of railroad have been abandoned in the past few years than have been built, while in 1887 nearly 13,000 miles of road was built, the country's pig-iron-producing capacity in that year having been about one-seventh the present capacity.

Making rough but sufficiently close estimates, there is more than 300,000,000 gross tons of steel in service in the United States, while the amount in service on the railroads is less than 100,000,000 gross tons. The productive capacity, in finished rolled steel, not ingots, is about 40,000,000 gross tons a year. As the railroads are already built and need to increase in efficiency rather than in size, while uses of steel outside of railroad employment present great possibilities, it is easy to see that the future of steel demand lies outside the railroads rather than inside. If two years of full steel production could be rolled and fabricated into the particular forms required by railroads, the railroad facilities would be doubled. That would be utterly absurd.

In the first six months of this year the railroads earned at the rate of 1.8 per cent a year on their tentative valuation, when the rates prescribed by the revision of last August contemplated their earning $5\frac{1}{2}$ per cent as a return on their value and $\frac{1}{2}$ per cent additional, looking to betterments, or a total of 6 per cent. In six months the railroads did not do one-third as well as was desired. Some claim that rates are too high, others claim that the railroads ought to spend a great deal of money.

The better view of the railroads is that they can help the industries of the United States by furnishing convenient and cheap service, by efficient operation of an investment kept down to the lowest possible notch, rather than by spending money. The less spending the railroads can get along with the better it will be for business in general, and the less we expect "business" to be made "good" by railroad expenditures in the next six months the less likely we are to be disappointed.

Meeting of the American Chemical Society

Report of the Sixty-Second Meeting of the American Chemical Society Held in New York, Sept. 6 to 10, 1921—Synopsis of the Papers Presented at the International, General and Divisional Meetings

THE sixty-second meeting of the American Chemical Society was held in New York, Sept. 6 to 10, 1921, with headquarters at the Waldorf-Astoria. In addition to the largest number of members ever present at a fall meeting of the society, leading chemists of Great Britain, Canada and other countries took part in the international meeting at the College of the City of New York and the other meetings held in the gymnasium and lecture rooms of Columbia University.

Council Meeting

The Council of the American Chemical Society met at 3 p.m., Sept. 6, in Rumford Hall of the Chemists' Club, with President Edgar Fahs Smith in the chair.

After the reading of the minutes the report of the committee on patents was taken up, which elicited rather lengthy discussion. In regard to the measure now before the U. S. Senate the committee reported against it on the ground that it might open the way to still greater abuses in blocking the development of American industries as practiced by German organizations previous to 1917. The conclusion was that while the Council was disposed to accept the report, it was of the opinion that more constructive measures should be included in any expression of the official opinion of the society.

The Sugar Section made an appeal that its status be changed to the Division of Sugar Chemistry and Technology of the American Chemical Society and its proposed constitution and bylaws were presented and found to be in order. By resolution the appeal was granted. The same action was taken in regard to the Leather Section, which now becomes the Division of Leather Chemistry.

Sir William J. Pope and Dr. Paul Kestner were nominated and elected by the Council to be honorary members of the society. The action was confirmed at the general meeting of the society on the following morning.

The invitation of the Pittsburgh Section to hold the September meeting in 1922 at that city was accepted with thanks. The April meeting in 1922 had already been determined to be held at Birmingham, Ala.

The editors of the several journals of the society and of the scientific and technological monographs were re-elected.

President Smith reminded the Council that the society was founded at the home of Priestley at Northumberland, Pa., and suggested that the Council bear in mind that 1926 will mark the fiftieth anniversary of the society and that a pilgrimage to the spot would be timely in connection with a spring or fall meeting which might be held in the neighborhood.

The secretary reported that on Aug. 1, 1921, the society had 15,157 members. This is about the same number as last year.

The advisory committee recommended that the officers of all divisions and sections be instructed to file with the society's news service all matters on which they desire publicity at general meetings.

Dr. John E. Teeple, on behalf of the Chemists' Club, suggested that inasmuch as the employment bureau which the club had conducted for many years had outgrown the club's facilities for housing and maintaining it, and in view of the wider scope which the bureau might enjoy if taken over by the society, the question of taking it over be considered by a special committee to be appointed for the purpose. It was resolved that such a committee, to consist of three members, be appointed, to report at the spring meeting.

The General Meeting

Three thousand chemists were present in the large gymnasium of Columbia University when the general meeting of the society was called to order by President Smith. Dr. John E. Teeple, the chairman of the New York Section and president of the Chemists' Club, was presented and in a brief greeting welcomed the sixty-second meeting of the American Chemical Society in the name of the members of the New York Section. The representatives of the sister society of the British Empire, the Society of Chemical Industry, who had come to join with American chemists in the discussion of scientific problems of mutual interest, also received a hearty greeting from their New York hosts. Dr. Smith responded for the society and expressed the gratitude of all present for the hospitality offered.

Francis P. Garvan, formerly Alien Property Custodian and now president of the Chemical Foundation, was introduced by Dr. Smith as "a gentleman to whom every chemist is deeply indebted for the services which he has rendered to the chemical profession." Mr. Garvan responded with an eloquent address on "Chemistry and the State," in which he made a dramatic appeal for chemists to accept the responsibility of teaching the people of this country the truth of Pasteur's statement that "Science is the soul of the prosperity of nations and the living source of all progress."

What the German chemist accomplished was not alone in his laboratory but in the forum of public opinion.

As an instance of the foresight of German chemical interests, Mr. Garvan told how a former American Commissioner of Patents, with the permission of an acting Secretary of State, had been induced to go to Berlin and to negotiate the patent treaty of 1909 by which Germany was released from working her chemical patents in this country. This Mr. Garvan characterized as the "crushing of the last hope of development of the organic chemical industry of this country."

Declaring that "German agents in America are once more plotting against us, he said: "If we allow Germany to stifle an American industry that would within a very few years make the United States absolutely safe, then, I say, it will have been through your neglect and temerity and failure to realize that it is your responsibility not only to search the truth but to preach it."

TELEGRAM FROM PRESIDENT HARDING AND RESOLUTIONS TO CONGRESS

Several items of interest came before the general meeting in its brief business sessions. A telegram from President Harding was read by Dr. Parsons. The President said:

Probably none of the materialistic sciences holds promise of so great contributions to human welfare in the coming generation as that which your organization represents. The developments of applied chemistry involve both a possibility of vastly increased horrors in human conflict and ultimately inestimable benefits to a peaceful civilization. Let us hope that a science so fraught with either good or vicious possibilities may be turned, through the wisdom of the nations, to the benefit and advancement of mankind.

Following the appointment of a committee, consisting of Drs. Chandler, Reese and Parsons, to frame a proper reply to the message from the President of the United States, resolutions to Congress were passed which requested that the coming disarmament conference should give due consideration to the subject of limiting chemical armament. The necessity of including in the permanent tariff law a temporary selective embargo against importations of synthetic organic chemicals was also urged.

MUSTARD GAS

Sir William J. Pope called attention to the peculiar philosophy of war. War is essentially the super-sport and anything which increases the sporting element is welcomed. Thus chemical warfare was condemned as inhumane, while preventive medicine was hailed as a blessing, in spite of the fact that preventive medicine made it possible to increase the army unit from 100,000 to 1,000,000 men and thus keep 20,000,000 men in the field. From this point of view, nine-tenths of the 15,000,000 combatants killed during the war died as a direct result of the use of preventive medicine. Con-

SIR WILLIAM J. POPE; GENERAL AMOS A. FRIES, U. S. A.
DR. CHARLES L. REESE, CHEMICAL DIRECTOR OF
THE DU PONT INDUSTRIES

trasted with this, chemical warfare constitutes a most humane weapon of war, and mustard gas is probably the most effective casualty agent known at present.

ORGANIZATION OF INDUSTRIAL RESEARCH IN CANADA

Prof. R. F. Ruttan described the workings of the plan for the development of industrial research in Canada. In 1916 the government of Canada by order in council established an Honorary Advisory Council for Scientific and Industrial Research, corresponding very closely in organization to the National Research Council for the United States and modeled largely on the Advisory Council for Scientific and Industrial Research in Great Britain, which has now become the Department of Scientific Research of the British Government.

Recognizing after investigation that liaison between research and industry could not be effected except by organized effort, a Central Research Institute was established near Ottawa. It is to be housed in a four-story building, 200 x 60 ft., with power plant and laboratories, the first \$100,000 being specially granted by the Cabinet to get the work under way during 1921.

The functions of the institute may be briefly described as follows:

- (1) It will be the Bureau of Standards for Canada.
- (2) It will carry on fundamental research in chemistry, physics, biology and related fields, investigations similar to those engaging the attention of university professors in scientific laboratories.
- (3) Investigations in biochemistry and bacteriology, both general and as applied to such industries as the fisheries and packing industries.
- (4) Investigations undertaken on recommendation of the Research Council from time to time to promote the utilization of the natural resources and valuable waste materials of the country.

The type of research work described under these four heads will be carried on by the permanent staff of the institute, associated with specialists engaged from time to time. This group of highly qualified investigators will form an advisory body for the industrial specialists who will be engaged by the Research Council or paid by the industries "to conduct inves-

tigation and standardization at the request of any group of industries in Canada concerning the materials used by them or of the products of such industries."

The difficult question of remuneration for valuable and patentable discoveries has been left largely to the discretion of the Research Council. The intention of the Council is to give a liberal share in the commercial rights of all such discoveries. Its function is to develop research, not to exploit it.

Smoker

The big ballroom of the Waldorf-Astoria was not large enough to care for the crowd that attended the smoker which began promptly at 8 o'clock on Wednesday evening.

After a number of songs and some instrumental music the stage was set for a sketch written by Ellwood Hendrick with the aid of Miss Marguerite Merington, author of "Captain Letterblir," "Snow White" and other plays, who acted as producer. In the performance *Uncle Sam* and his secretary *Civil Service* received *John Bull* and *Miss Canada*, who arrived by airplane to attend the chemical meeting. They discussed their varied difficulties in chemical industry and *Uncle Sam* declared that his worst trouble was the fly-by-night speculator who bought control of chemical works, dismantled research laboratories, made the research reserves appear as available for dividends, then got out from under. *John Bull* said he lost some of his leading industries through just such persons. *Uncle Sam* thought it might be well if the chemist should assert himself more than he does—at which point an *American chemist* broke his way past a garrulous *Italian waiter* and wanted to see *Uncle Sam*. He was taken for a lunatic and made to sit down when an *English chemist* came in from the audience and wanted to see *John Bull*. As soon as the authorities recognized that they were chemists they gave them a hearing. They wanted to go to the meeting and their employers would not let them. This amazed the authorities, but it was a fact; their employers were afraid they might give something away. The powers concluded to get to the bottom of the question and concluded that the responsible party to reach was old *Quickturn Capital*, a man of vast wealth and arrogance who was hard to find and hard to deal with when found. At this point old *Q. Capital* burst into the apartment. He had seen a couple of chemists come in there and he wanted to fire them. He was resolved to cut out all the deadwood. Even when he learned who his hosts were he persevered in his autocratic ways, declaring that he had got what he wanted out of his chemists and now he was through with them; they were neither raw material nor finished product nor sales force nor administration. "If you ask them what they are doing," he exclaimed, "they give you a lot of hot air. They stall . . . and they eat up dividends." He soon showed himself to be unconscious of any obligations or responsibilities other than to make a good showing and then sell out. He was therefore turned over to the chemists, who squirted information into him. A telegram arrived telling him the works were shut down and they did not know what to do because the research laboratory had been closed. Then followed a transformation scene in which he begged the chemists to see him through, and all concluded to go to the meeting together.

Aside from the parts taken by *John Bull* (J. D. H.

Randall), the English chemist (W. L. Cofren of the U. S. Industrial Alcohol Co.), and one of the alchemists, J. Lainson Wills, the characters were all represented by members of the staffs of CHEMICAL & METALLURGICAL ENGINEERING and other McGraw-Hill publications. *Uncle Sam* was Mr. Gordon, now business manager of *Ingenieria Internacional* and formerly of CHEM. & MET.; *Canada* was Mr. Shaver of *Engineering News-Record*; *Civil Service* was Mr. McNamara of *Engineering News-Record*; the *Italian waiter* was our own business manager, Mr. Fellner; the *American chemist* was Mr. Spooner, also of CHEM. & MET., and *Quickturn Capital* was Dr. Hendrick. The two alchemists who carried the banner were respectively Mr. Wills and Mr. Kirkpatrick, our assistant editor.

The play was followed by two professional acts, and the singing of several parodies of songs relating to various prominent members and visitors concluded an enjoyable evening.

International Meeting

The international meeting was held Thursday, Sept. 8, in the Great Hall of the College of the City of New York. Dr. Edgar Fahs Smith presided. "Chemistry and Civilization" was the subject expounded from different viewpoints by Drs. Charles Baskerville, A. D. Little, L. H. Baekeland, Sir William J. Pope, W. R. Whitney, C. E. K. Mees, Ernst Cohen and W. D. Bancroft.

SCIENCE AND CIVILIZATION

Dr. Charles Baskerville spoke on "Science and Civilization," with particular reference to the value of chemistry as a civilizing influence. He called attention to the remarkable progress of the world during the past 150 years, stating that more had been done during that time than in all previous centuries combined. After outlining the development of learning from early times and proving the part which research and science had in this development, Dr. Baskerville concluded by stating that chemistry must play a great rôle in preparing the "cement" which will bind mankind in brotherhood.

ENERGY: ITS SOURCE AND FUTURE POSSIBILITIES

In his paper on "Energy: Its Source and Future Possibilities," Dr. Arthur D. Little outlined the vast work to be done to brace up our broken civilization and the immense requirement of energy to accomplish the undertaking.

The energy available from sources at hand is inconceivably greater than human needs—if we but knew the art of capturing it. There is, for instance, the radiant energy of the sun, of which Sir Oliver Lodge says the earth receives but one one-hundred-and-fifty-millionth part. It is only three small calories per minute per square centimeter of the earth's surface; but Ciamician has calculated that a surface of only 10,000 square kilometers, assuming six hours as the effective day, receives in a year the quantity of heat that corresponds to the burning of 3,650 million tons of coal, or more than double the world's production. The desert of Sahara with its 6,000,000 square kilometers receives daily the solar energy equivalent to 6 billion tons of coal. The world awaits the genius who will convert the radiant energy of the sun into electric current. Of the minute portion of solar energy received by the earth, only one three-hundredth part is stored up in plants. They, nevertheless, according to Ciamician, produce 32,000,000,000 tons of vegetable matter which,

if burned, would develop a quantity of heat equal to that derived from 18,000,000,000 tons of coal.

The energy of the earth's rotation has thus far been used only in the application of the gyroscope. That of the wind and waves is too uncertain and diffused to encourage extensive exploitation. There are two extensive tidal power developments under construction, at St. Malo in France, and at the mouth of the Severn River in England. The latter will provide 437,000 continuous horsepower. The continuous tide power of the British Isles has been computed to be 2,250,000. The capital requirements for such installations is naturally more than double that required for continuous falling water.

In Italy a 30,000-hp. steam turbine installation has been made for which the energy is derived from steam issuing from the vents in the side of a volcano.

Sir Ernest Rutherford has said that "the human race may date its development from the discovery of a method of utilizing atomic energy."

Our civilization is based on coal. In 1913 the world's resources were summarized as follows: Including 3,000,000 units of lignite, the total reserves are 7,400,000 units, of which 5,000,000 are in North America, 1,280,000 in Asia, 784,000 in Europe, 50,000 in Africa, and 25,000 in South America.

One-tenth of the population of the United States is dependent on natural gas. In 1917 we used 800 billion cubic feet and wasted 800 billion more. In 1920 our production was below 650 billion. Our misuse of this is an indictment of individualism.

Of petroleum the United States now produces 70 per cent of the world's supply. Our reserves are nearing depletion and we can scarcely maintain the present rate for twenty years more. We need an intelligent economic petroleum policy in the United States and the power to enforce it.

Shale oil is a resource for the future, and so is our peat supply, and so too are the striking possibilities in the production of power alcohol.

The water power of the United States is sufficient to drive every factory and light every building in the country, but development is inhibited by the cost to construct, inasmuch as bond interest represents 77 per cent of operating costs.

Coal must remain for generations our chief energy resource.

THE ENGINEER: HUMAN AND SUPERIOR DIRECTION OF POWER

"The forces of nature are the most enduring wealth of mankind. To know their laws and to learn how to apply them has made of a puny little being of about 130 or 200 lb. of flesh and bone—three-fourths of which is merely water—a giant of which Gulliver's tales have no equal." This was the opening remark of Dr. Leo H. Baekeland, in his address on "The Engineer: Human and Superior Direction of Power."

He stated further that there are few who fully realize that a co-ordination of the thoughts and work of the chemists and chemical engineers is indispensable for the successful practical progress of the chemical industry. The chemist is a scientist. By direct observation or experiment, and aided by theoretical reasoning, he tries to correlate observed facts until he believes that he is warranted to generalize thereon. He thus helps to discover new truths or laws of nature which in their turn will permit him to predict facts

in advance. But the experience of many a scientist has been confined exclusively to laboratory work, or to purely chemical subjects, and this is frequently the reason for his weakness in dealing with practical matters. The ways of thinking and acting of a chemist and those of an engineer are often along decidedly different points of view. Yet, if these points of view can be compromised or harmonized, they bring forth good chemical engineering.

CHEMISTRY AND LIFE

Sir William J. Pope, in speaking of chemistry in relation to life, said that during the last fifty years the organic chemist has forged for himself new tools in which low potential energy is applied and induced to take part by the presence of the so-called catalyst. Obviously organic chemistry is approximating in its experimental methods those which occur exclusively in plant and animal life.

When we possess full working details concerning the plant leaf process for converting carbon dioxide and water into formaldehyde and oxygen by utilizing the sun's energy, when we can make indigo and quinine by the identical processes carried on in the plant, chemical technology will be an entirely different proposition from the one it now represents.

We must also recognize that wide economic differences exist between a self-contained European country and others which have the whole tropical world within their range, and that entirely distinct types of problems are in consequence presented to their chemical technologists. It is for us to realize all the bearing of these differences upon chemical science and chemical industry and to see that we neglect no means for applying the great opportunities within our reach in the service of mankind and of our respective countries.

THEORIES

A system of theoretical mythology was advanced by Dr. Willis R. Whitney, in an address on "Theories." Whitney avers that Prometheus was the first theorist, and his daring conceptions and swift conjectures gave early man many of his comforts and necessities. But unfortunately, his theories were too daring, often disregarding fact, and he was finally chained to a mountain top so he could keep at least one foot on the ground. His slow-witted brother Epimetheus was also a theorist, but better, he was in addition the first experimenter. His first investigation consisted in opening Pandora's box, and disclosed not woes to afflict the race, as claimed by some, nor blessings ever lost, as maintained by others, but in fact nothing but enigmas, which the finder and his descendants have since been striving to solve. All theorists and experimenters have since been disciples of Prometheus and Epimetheus, and all theories God-given or earth-born are of value, even if the latter sort are finally disproved, for they lead to further experiments.

RESEARCH APPLIED TO THE WORLD'S WORK

If we all had enough there would be no need for unrest and hence no great inducement for research and advancement. This is the first major thought in C. E. K. Mees' address, "Research Applied to the World's Work." However, with education comes a demand for the opportunity to insure one's own future. Fail to satisfy this demand and a chaos of unrest will follow.

The modern world, the world as it is, is the creation

of a very few years of technical discovery and development. Modern wealth, especially of the United States, has been produced as the result of technical and scientific progress in research.

The function of a research laboratory is "to supply the technical information on which an industry is operated." This applies as well to sales or utilization of products as to production. It thus serves as the intelligence department in industry, supplying the information on which decisions are made, not only those of advance or new development, but also those to withdraw from or avoid technically unpromising lines.

PROBLEM OF DIFFUSION AND ITS BEARING ON CIVILIZATION

Dr. Ernst Cohen, famous Dutch chemist, and professor of chemistry at the University of Utrecht, addressed the meeting on the subject of "Diffusion and Its Bearing on Civilization." The history of the process of diffusion was traced from its discovery in a French abbey in 1770 to its final explanation by van't Hoff in 1885. The development of physical chemistry may be said to have dated from the work of this great Dutch chemist. Prof. Cohen declared that realization of the important rôle of diffusion in the processes of living matter is the foundation on which we may hope some day to build up a complete understanding of life's processes. In concluding his address, the speaker referred to the work which is being done at the University of Utrecht in connection with the accurate determination of the coefficients of diffusion. He intimated that the final publication of the results of this research will reveal that many of these important physical constants, as previously determined, are in error because they were obtained in buildings and apparatus subject to vibration.

CATALYSIS: THE NEW ECONOMIC FACTOR

War's destruction of capital must be restored if nations are to continue to progress, and Prof. Wilder D. Bancroft declared in his address that chemistry, better applied through the use of catalysis, is the most promising means of accomplishing this end. Catalytic agents may prove to be the important economic factors which will some day produce liquid fuel from coal or light without waste of heat and energy, scientifically control the rain from the clouds, and finally render solar and atomic energy completely useful to man.

Organic chemistry in the past has failed to use catalysis to any great extent, but the work of Sabatier, J. J. Thompson and the recent data of Reed of Johns Hopkins indicate that the trend is in this direction.

Presidential Address—Progress in Chemistry

Those who were fortunate enough to hear the presidential address of Dr. Edgar Fahs Smith cannot but marvel at his remarkable insight into the history of chemistry in America. Choosing as his text the words of Berthollet, "Chemistry has become regularly and philosophically progressive," President Smith traced step by step the inspiration and impetus given to those who have contributed to the advance of American chemistry. Over a century and a quarter ago the pioneer chemical society of the world—the Chemical Society of Philadelphia—was assembling and disseminating information relative to the manufacture of niter, even as American chemists of 1914 to 1918 harkened to the call of their country in its hour of peril.

However, not all of the thoughts of our chemical fathers were of the implements of warfare, for, as Dr. Smith affirmed, many domestic industries had their conception in the minds of these pioneers. The making of sal-ammoniac, glauber's salt, oil of vitriol, prussian blue and numerous other pigments, and in fact even a few American dyes was well under way over a century ago.

Furthermore, these early investigators "felt it their duty to publish and disseminate the knowledge they were acquiring through their investigations. They did not seek to hide their discoveries. They believed in publicity. They desired that their science might receive honor, but also that their country might be assisted in winning its way among the nations looking down upon it.

"My desire is that we have no East, West, North or South in chemistry, but one united body from all sections eager to carry the science into every walk of life—even into the halls of government, that their occupants may understand how intimately chemistry is interwoven with the laws and welfare of the land."

Division of Dye Chemistry

The Dye Division convened Thursday morning with A. B. Davis in the chair and R. Norris Shreve as secretary.

The meeting was well attended and the papers contained information of value.

A few of those having general interest are noted here.

W. F. Prescott, of the Sherwin-Williams Co., spoke on the dye situation in Canada. He said there were 80 woolen mills, 20 cotton mills, 80 knitting mills, 8 silk mills, 130 leather plants and 50 paper plants in the dominion, producing about \$220,000,000 worth of goods annually, against about \$55,000,000 worth in 1911. In regard to dyes, they do not expect to produce intermediates or many varieties of dyes. Their imports for the year ended March 1, 1921, were \$630,000 worth from England, \$2,500,000 from the U. S. and \$200,000 from Germany and Switzerland. He was of opinion that considerable German dyes came in as Swiss.

J. P. Schmidt, of the Monsanto Chemical Co., presented a paper on lakes prepared from para-phenetidine. There are fifteen to twenty colors of this type made from phenacetine as the basic intermediate. Para-phenetidine coupled with beta-naphthol gives a beautiful bluish red which, precipitated on chalk, was exposed to varying weathers for three months during the spring and held remarkably well, showing great fastness to light. It is somewhat soluble in oil, which makes it available for shoe polish, wood stains, etc., or wherever solubility in oil is desired. By diazotation the solubility in oil is overcome and a series of colors from orange to bluish reds is obtained.

E. R. Harding, also of the Monsanto company, spoke on the synthesis of anthraquinone from phthalic anhydride and benzene. The only available crude for anthraquinone heretofore has been anthracene, but the claim has been made that the removal of this crude, needed for many of the most desirable vat dyes, from pitch renders the pitch unavailable for roofing and road making.

Dr. J. L. Bulloch, of the Uniform Chemical Products Co., read a paper on "Improving the Yields and Quality of Our Dyes and Reducing their Cost." He emphasized the need of thorough knowledge of intermediates and the requirement for greater precision in quality tests.

Dr. L. A. Olney, of the Lowell Textile School, told of the "Extraction Process for Degreasing Wool" instead of the usual method of scouring by emulsion with soaps. A plant of sufficient size costs several hundred thousand dollars. The Arlington Mills, which has the only installation in the country, applied an invention of Emile Martens of Providence, which has proved excellent, using petroleum naphtha. It has been in use for twenty-five years without an accident, all the potash is recovered and over 1,000,000 lb. of raw wool per week is treated. The wool so extracted is much purer than that scoured in the ordinary way with soap and it takes up dye so fast that it may not be successfully dyed when mixed with that scoured in the usual manner.

Dr. Leon W. Parsons and W. A. McKim, of the Massachusetts Institute of Technology, contributed a paper on "The Effect of Dye Structure on Dye Adsorption." This was in accord with Langmuir's theory in regard to the relation of the structure of molecules to color and shade and the effect of fields of force due to internal structure extending beyond the confines of the molecules, on their behavior.

Dr. J. Merritt Matthews, editor of the *Color Trade Journal*, asked, "Is an Export Trade Necessary to Our Dye Industry?" The United States consumes about 12 per cent of the world's production of dyes. No embargo can last over a few years. Is there enough in the American market to keep the industry flourishing? Some dyes can be made profitably under fair conditions, but others are not used enough to make it worth while to produce. He held it desirable to recapture foreign trade which is now fading away and noted the Department of Commerce is ready to co-operate.

Oscar R. Flynn, of the Walderich Bleachery, discussed the fastness of dyed textiles to stoving, which would appear to be the opposite of fastness to light, but which he regards as having to do with conditions of air which envelops the fabric, some of which is prevented by containers from the usual measure of diffusion.

Gaston du Bois spoke on the features of cost and pointed out the effect of high costs on exports. The United States exported dyes as follows:

1917	\$7,548,000	January, 1921,	\$1,292,709
1918	15,266,000	February, 1921,	467,764
1919	15,728,000	March, 1921,	670,261
1920	29,823,000	April, 1921,	365,010

More than half of the above went to Asia and South America, but owing to high costs Germany is rapidly recapturing those markets. Our costs are from two to three times those of Germany today. Wages and salaries are seven times as high, but these are unimportant compared with volume, yield and experience. He favored a good downward revision of investment accounts.

C. R. DeLong of the Tariff Commission spoke of "The Present Status of the Domestic Coal-Tar Products Industry." From 1917 to 1920 inclusive the output of the United States was approximately doubled. Indigo increased from 275,000 lb. in 1917 to 18,000,000 lb. in 1920—nearly double the pre-war importation. Average price in 1917 was \$1.24, against 74c. in 1920. Now it is 40c. Vat dyes other than indigo increased from 15,000 lb. in 1917 to 1,160,000 in 1920. Coal-tar medicinals doubled, to 5,000,000 lb., in 1920, and perfume materials increased from 19,000 lb. to nearly 100,000 lb. in 1920. Synthetic resins reached 4,500,000 lb. and synthetic tanning materials 3,000,000 lb. Triphenyl and

tricresyl phosphates were introduced as camphor substitutes in pyroxylin plastics.

In the coal-tar products industry between 10 and 11 per cent of the men employed are chemists. The cost of research from 1917 to 1920 inclusive has been materially over \$15,000,000.

Greatly needed in the dye industry is a standardization of dyes and a revision of the present conflicting and bewildering nomenclature of these products.

Division of Industrial and Engineering Chemistry

The meetings of the Division of Industrial and Engineering Chemistry were held Wednesday, Thursday and Friday. There was a symposium on filtration, one on gases and fuels, and general papers.

SYMPOSIUM ON FILTRATION

D. R. Sperry acted as chairman of the Symposium. Sixteen papers were presented.

In his paper on the fundamental laws of filtration with suggestions regarding research work, Mr. Sperry called attention to the fact that filtering has not been developed on a scientific basis and that the fundamental laws must therefore be studied.

The three essentials involved are the filter base, a difference of pressure, and a filter or mechanical device for containing the operation. Studies have shown that the flow of liquid through a porous mass varies directly as the pressure and inversely as the thickness of the cake. One series of tests led to the conclusion that the flow varies as the first power of the pressure, denoting capillary phenomenon.

Eustice A. Alliot, a visiting member from Great Britain, gave another of the papers on fundamental data which he has worked out in the study of washing and washing ports used with chamber and frame types of filter presses. The following paragraphs cover a short abstract of his work.

Nominally, washing consists of the displacement of mother liquor from pores between particles by an equal volume of wash, in which case little mixing of wash and mother liquor takes place. Such perfection is theoretical, and various disturbing factors enter, the chief ones of which are:

1. Adsorption,
2. Capillary diffusion,
3. Formation of chemical compounds,
4. Colloid formation on the removal of electrolytes.

Adsorption is the unequal distribution of the solubles at the boundary between solid and liquid phases of the cake owing to surface energy effects. A large excess of solubles is retained in the surface film and will not wash away. The effect is proportional to the area of boundary surface and is most important in finely divided or gelatinous precipitates. The washings may be graded and used in succession, finishing with a small proportion of pure wash.

Absorption of mother liquor by capillary diffusion into the pores of the cake particles requires a dilute wash to be effective and a time factor comes into play. In the case of iodine and charcoal, weeks may be required before an equilibrium is established. The effects are similar to but more complex than adsorption, involving more wash and longer time.

Chemical combination with the substance of the filter particles where such compounds are stable only when the concentration of the liquid phase is in excess of the critical amount often occurs in fine chemical

manufacture. In such conditions the excess of wash required varies directly as the quantity of solubles retained and inversely as the critical concentration.

Some precipitates are held in the coagulated state only in the presence of suitable electrolytes. When these are removed by wash water a finer structure of cake results or it may even disappear entirely. Stage treatment with washes of graded strength may be used so that the entering wash always contains a little electrolyte.

In obtaining best results for thorough washing, it appears necessary to have a plate and frame press, a means for air elimination, and the wash must leave at the top of the press so that the cakes remain immersed in the bath of wash eliminating unbalanced hydrostatic head.

It cannot be too clearly understood that good results depend not merely on the mechanical arrangement of the press but almost more on the attention paid to getting proper physical condition of the material and delivering it in a suitable manner to the press. Every detail of the operation should be correct.

OTHER PAPERS IN FILTRATION SYMPOSIUM

Alvin Allen Campbell, of the Newark Wire Cloth Co., compared the animal and vegetable materials for the production of filter cloth with the metals. Cotton duck has been used, but together with wool, hemp, jute, etc., is too slow. Strength is an important essential of a filter base, but the greatest difficulty encountered is with leakage.

H. D. Atkins described an automatic filter press which is pivoted near the center of its length. When the cake has been formed the press is turned on the pivots to a vertical position, so the cake may be removed without opening the leaves.

H. A. Vallez, of Bay City, Mich., described a new rotary filter which consists of a cast-iron cylindrical shell arranged in the horizontal position and completely housing the filter elements which revolve on a hollow shaft. Sprays remove the cake from these elements and it falls to a screw conveyor on the lower side. The driving gears are placed at one end of the casing and the filtrate discharge at the other.

H. C. Beckman, of the De Laval Co., outlined the four uses of centrifugals as pertaining to extraction, separation, clarification and filtration. Filtration by centrifugal was first tried in perforated drums, but it was found that the cake became quickly compressed until it was impervious. The non-perforated rotor consisting of a series of drums or shelves mounted on a vertical axis and revolving at a speed of 6,000 r.p.m. was then developed.

Arthur Wright classified industrial filter media, in the main consisting of fabrics used with corrosive and non-corrosive materials. Cotton is largely employed for non-corrosive liquids. There is need for standard methods in specifying filter cloth. It should be known by the size of yarn, the number of threads per inch in warp and weft, and by the weight per unit of area.

Cotton and wool fabrics will not stand strong caustic solutions. Wool will resist acids, though cotton is sometimes better where necessary care is employed. Tests should be made to determine the best filter medium for each problem.

E. E. Finch spoke on the development of filtermass filters in the brewing industry and the subsequent applications for clarifying vinegar and food products.

C. P. Derleth and G. M. Hickey covered the use of FilterCel as an aid to filtration and its specific application in several industries.

G. D. Dickey described the machines marketed by the Industrial Filtration Corporation, showing numerous slides of all types.

Robert C. Campbell gave an illustrated talk on the apparatus manufactured by the United Filters Corporation, which includes the Sweetland and Kelley presses and the American continuous vacuum filter.

SYMPOSIUM ON THE CHEMISTRY OF GASES AND FUEL

The four principal topics for discussion at the symposium on the chemistry of gases and fuel were: (a) Coke-oven problems, (b) low-temperature carbonization, (c) gas works control, and (d) gas analysis and its applications. C. H. Stone of the Rochester Gas & Electric Co. acted as chairman, R. S. McBride, secretary.

According to F. W. Sperr, Jr., who opened the discussion on coke-oven problems, the fundamental research needed is now more appreciated than ever before. Knowledge of the constitution of coal is one of the outstanding needs in connection with the fuel supply itself. In the case of coke the past work has dealt mainly with the question, "How to make it?" Now the need is to answer, "What is it?" Specific heat and heat conductivity data, among other physical constants, are much needed, as are further facts as to the sulphur forms in both coal and coke. The byproducts other than coke of course afford an unlimited field for investigation.

Low-temperature carbonization of coal was discussed by Horace C. Porter. In his opinion the largest opportunity today for low-temperature work is as an adjunct to gas works, especially where the complete gasification of the fuel can be had through some "double-gas" system, the coke from the first stage being used in a form of water gas machinery for the second.

The discussion of needed carbonization investigations included reference to the study of the thermal history to which fuels are subjected during processing and extensive investigation needed for determination of thermochemical data. It was made clear by Dr. Fieldner that only through a full knowledge of how coke of various types can best be used will it be possible to persuade the blast-furnace operator to take any type of coke which can best be made in view of the current market requirements for byproducts.

Chemistry in gas works control was discussed by E. C. Uhlig, who pointed out the large opportunity for further chemical investigation in theoretical lines which undoubtedly would afford sound basis for industrial development of the future. C. H. Stone brought out clearly the numerous miscellaneous problems which are presented to the gas works chemist for solution.

Arthur L. Davis described two methods for determining light oil in coke-oven gas. The first covered the absorption of the light oil in charcoal, but distilling with cresol or cresylic acid instead of glycerine. The second is a method of absorbing light oil in cresylic acid which has been developed in France on a commercial scale. A plate and bell tower with ten plates and bells is used with countercurrent flow.

George C. Brown, Jr., gave an exhaustive paper on the chemically controlled automobile. He showed methods of analysis, stated that 30 per cent of the gasoline passes out the exhaust in unburned gases and

finally that too much stress had been laid on the mechanical features of the gas engine when the big losses involved chemical engineering. In another paper Mr. Brown gave short-cut methods for calculating the temperatures of combustion.

The members present voted to request the secretary of the Division of Industrial and Engineering Chemistry to undertake to determine whether the organization of a section on the chemistry of gases and fuel would be justified, and if so to formulate a request to the proper officers of the society.

GENERAL PAPERS

E. F. Collins, of the General Electric Co., abstracted an able paper on electric heat for thermal processes, showing numerous slides of industrial electric appliances. He stated that considerations of other features than the cost per B.t.u. play an important part. Electrical heat gives safety, more uniform temperature and economy of labor in operation.

Robert E. Wilson gave data determined and collected on the humidity equilibria of common materials. Tests were made at M. I. T. on substances with the humidity of the air at 15, 30, 50, 70 and 95 per cent. Curves plotted for each substance showed that most common ones lie between the sulphuric acid curve and the amyl alcohol curve.

Robert E. Wilson, William H. McAdams and M. Seltzer have made a study of the frictional resistance to the flow of viscous liquids through pipe elbows and compiled data from a series of 200 tests. There is no important difference between the flow in common smooth pipe and glass tube. In turbulent flow the resistance of an elbow was confirmed to require an additional correction of length of pipe corresponding to 35 pipe diameters, while with viscous flow only 4 or 5 pipe diameters need be added to length to correct for resistance of the elbow.

P. C. Haeseler described a new process developed at Columbia University and later tried on a commercial scale for the manufacture of sulphuric acid. It is noted that selenium is involved in the reaction but is not a contact or catalytic agent. The reaction used is

Selenium is roasted in a furnace to SeO_2 and passed into a tank of water to form H_2SeO_3 . This is slowly sprayed in very finely divided state into the top of a chamber where the SO_2 gas is introduced. Sulphuric acid, about 50 per cent strength, forming a slurry with selenium, is drawn off at the bottom and passed through rotary filter having Monel metal screen. The filtrate is ready for the market as 50 per cent H_2SO_4 or sent to the concentrating plant. The sludge of selenium is returned to the roaster.

C. J. Rodman determined that mineral and chlorinated oils were ruptured with an electric arc of 100,000 volts, 333 cycles, by temperature and pressure effects rather than by sympathetic vibration.

H. P. Holman abstracted his paper covering the effects of waterproofing materials upon the tensile strength of cotton yarn. Bituminous materials are the best treating compounds as regards the effect on tensile strength. Raw drying oils are not so good as those mixed with metallic compounds. Rosin reduces tensile strength and yarn treated with cold vulcanized rubber shows an immediate and marked deterioration. Oleic acid causes deterioration and lead oleate is poorer than other oleates.

E. C. Bingham held the chair for the discussion of special order on world standardization, which was an informal symposium on the adoption of the metric system in the U. S. The report of the committee for the adoption of standard metric units for the purchase of chemical apparatus and supplies showed that out of 600 universities and colleges questionnaired about 150, including large institutions, have signified their intention of purchasing by the metric system. Twenty-four dealers are willing to supply in both English and metric units. Some of these will feature the fact in their advertising. W. A. Noyes moved that the division ask the advisory committee of the A.C.S. to indorse House Bill 10. The slogan for the chemists is to be, "Pure chemicals purchased by the metric system, in standard packages."

The officers and committees of the division for the coming year were elected as follows: Chairman, Warren K. Lewis; vice-chairman, D. R. Sperry; secretary, H. E. Howe; assistant secretary, E. M. Billings; executive committee: W. F. Hillebrand, Edward Malinckrodd, Jr., F. M. DeBeers, Alexander Silverman, Herbert R. Moody, C. E. Coates, W. D. Richardson, F. E. Breithut, C. O. Johnes.

Division of Physical and Inorganic Chemistry

A well-rounded program of nearly fifty papers occupied the attention of the physical and inorganic chemists during Wednesday, Thursday and Friday. H. N. Holmes was chairman and S. E. Sheppard secretary.

It is impossible here to summarize all of the many papers presented but a number of the most interesting are briefly referred to in the following paragraphs:

The increasing interest in this field was evidenced by the presentation of papers on the transitional temperature of gelatin and the swelling and gelation of gelatin by Dr. B. H. Bogue of Mellon Institute; the fluidity-pressure curves of gelatin solutions by Dr. S. E. Sheppard and his co-workers of the Eastman laboratories, and on the plasticity of colloids by Prof. E. C. Bingham of Lafayette College and Prof. Robert E. Wilson of Harvard University. Dr. Bogue presented evidence favoring a concentration-variable transition area between the sol and gel states. In the discussion E. T. Oakes stated that certain of his data indicated a concentration-invariable transition point. Dr. Sheppard declared that he had obtained confirmation of both points of view but found difficulty in bringing the two into complete harmony. Bingham pointed out the co-ordination of Bogue's data with those obtained by R. A. Gortner on flours and by himself on clays.

Messrs. Lichtenwalner, Flenner and Gordon sought to determine the maximum adsorption of solutions of calcium, magnesium and potassium acid phosphates by iron hydrogel and aluminum hydrogel. The sulphates of these metals were also used with iron gel. In both instances the calcium salts were adsorbed to the greatest extent, while those of potassium were least adsorbed.

Electrometric titration methods were used by W. Mansfield Clark and his co-workers in a study of oxidation-reduction equilibrium with a view to developing a series of indicators similar to the acid-base indicators of Lubs and Clark. The reduction of various indigo sulphonates, methylene blue and its homologues, and of the different indophenols by means of titanium citrate were studied. In general p_H was held constant for each determination by the use of a buffer agent.

Prof. Harold A. Fales and Harold E. Robertson of

Columbia University ask the question: Are electrolytes completely ionized at infinite dilution? The preliminary report on their work on this subject apparently answers this question in the negative.

Dr. Saul Dushman of the General Electric Co. and Miss Mary A. Andrews reported on the reaction between tungsten and hydrocarbon vapors. This phenomenon is of importance, because the oil pumps used for evacuating incandescent lamps give off hydrocarbon vapors which under the conditions of high temperature and vacuum have a deleterious effect on the tungsten filaments. Using naphthalene vapor, it was found that at constant temperature of filament and pressure of naphthalene the conductivity of the filament decreases uniformly with the time, until a minimum point is reached at which, as shown both by the hydrogen evolution and chemical analysis of the filament, the filament is completely converted to W_2C (corresponding to 3.18 per cent C). The conductivity of this carbide is only 8 per cent of that of pure tungsten. Further decomposition of the naphthalene leads to the formation of the higher carbide WC , the conductivity of which is about 40 per cent of that of pure tungsten.

Dr. A. P. H. Trivelli, with E. P. Wightman and S. E. Sheppard of the Eastman laboratories, reported on the results of the pioneer work they are doing in the investigation of the photochemical properties of photographic emulsions.

In order to do away with the dielectric, which is one of the principal causes of the unreliability of commercial ozonizers, Dr. F. O. Anderegg of Purdue University has studied a high-frequency discharge apparatus for the production of ozone. Its chief advantage lies in the fact that it is impossible to maintain a high-frequency arc. An aluminum tube 5 x 190 cm. with a concentric wire was used for the discharge. Current was supplied up to half an ampere and 7,000 volts at about a million and a half cycles frequency by a small Tesla coil. The highest yields were obtained with a rather large wire provided with numerous small points so that the discharge should be made up of many brushes. The ozonized air contained but small amounts of nitrous oxides, although on raising the voltage till the discharge was filled with sparks about 0.02 per cent was obtained. Numerous curves have been worked out showing the relationships between the different variables, which are usually similar to those obtained in low-frequency ozone production.

Prof. Alan W. C. Menzies described an ingenious differential thermometer which he devised for use in ebullioscopy. In its simplest form it consists of a small glass U tube filled with water. The lower arm of the tube is closed to form the bulb of the thermometer, and to other, which has a closed reservoir at its tip, consists of a carefully calibrated capillary tube. A degree rise in temperature will cause as much as 200 mm. rise in the water in the capillary.

Claude H. Hall, Jr., has repeated and confirmed the work of Patterson on the decolorizing action of bone black. By extraction of hydrochloric acid washed bone black with sulphuric acid an extremely active decolorizing agent was prepared. By precipitating this compound on wood charcoal or other porous substances, a material identical in chemical action with bone black was obtained. This active principle was found to be a mixture of nitrogenous decomposition products of bone cartilage.

C. R. McCrosky and A. J. King discussed the prepara-

tion of the selenides of ammonia. They have found that when ammonia is present in excess in the reaction between ammonia and hydrogen selenide, a colorless liquid containing selenium equivalent to normal ammonium selenide is formed. This compound freezes at 10 deg. C. On losing ammonia it changes to a white crystalline compound corresponding to the biselenide, NH_4HSe .

R. A. Gortner and W. F. Hoffman, in a paper entitled "An Interesting Colloid Gel," pointed out that gelatin, agar agar, and even silica gels were not always satisfactory as standard gels due to variation in quality. It was pointed out that a rigid gel can be prepared from dibenzoyl cystine containing as little as 0.15 per cent of the compound. Viewed by dark field illumination, this is apparently a crystal gel. It is suggested that this material may assist in studies regarding gel structure.

Dr James W. McBain, professor of physical chemistry at the University of Bristol, England, in his studies of the adsorption of toluene and acetic acid by carbon has obtained results which appear to substantiate the theory that adsorption consists in the formation of a monomolecular film entirely covering the surface of the carbon. By diminishing the temperature difference between the carbon and the toluene, equilibrium was reached between the two and a definite value obtained

for $\frac{x}{m}$; the measure of adsorption.

The preparation of a ferric hydroxide gel as an absorbent for gas defense was described in a paper by Messrs. Robert E. Wilson, William B. Ross and Leon W. Parsons. Using 6 per cent solutions of ferric chloride and sodium hydroxide, a dark brown gel was obtained by complete precipitation. After washing by decantation, it was filter-pressed and vacuum-dried to a moisture content of about 10 per cent.

NEW OFFICERS ELECTED

Following the formal presentation of the papers, a business session was called. The nominating committee reported the following officers for the new year, and they were duly elected: Chairman, Dr. S. E. Sheppard; secretary, Prof. Robt. E. Wilson; executive committee, Messrs. Blum, Hildebrand, J. H. Mathews, and Weiser.

TO CONTINUE THE "JOURNAL OF PHYSICAL CHEMISTRY"

At the meeting on Friday the chairman, Prof. H. N. Holmes, called the attention of the division to the statement by Dr. Bancroft that he would be unable to continue the publication of the *Journal of Physical Chemistry* after December of this year. It was the opinion of the meeting that this action would be of the nature of a catastrophe to investigators in the field of physical chemistry. The chairman appointed a committee consisting of Messrs. Bingham, Abbot, Menzies, Kendall and McBain and instructed them to report a definite plan of action. This committee subsequently recommended that the division urge Dr. Bancroft to continue to edit the journal for another year and that in the meantime a representative committee should be appointed to devise a permanent plan for continuing this or some similar journal. It was suggested that the committee look to the British for co-operation with the idea of creating an international medium. The report of the committee was accepted and plans were formulated for organizing the work of the large committee.

Division of Leather Chemistry

The meetings of the Division of Leather Chemistry were held during Wednesday, Thursday and Friday, Sept. 7 to 9, under the chairmanship of John Arthur Wilson.

Among the papers presented were the following:

COLOR MEASUREMENT OF VEGETABLE TAN LIQUORS

The difficulties encountered in attempting to measure the colors of vegetable tan liquors were discussed in a paper sent in by Prof. Henry Richardson Proctor. The applications of the colorimeter, tintometer, brown-yellow glasses and iron alum solutions were all considered. It was suggested that the most satisfactory method might be to determine the depth of solution necessary to absorb one-half of the light from several different parts of the spectrum.

COLOR VALUE OF TAN LIQUOR AS FUNCTION OF p_H

John Arthur Wilson and Edwin J. Kern found that the natural coloring materials in vegetable extracts act like indicators with changes in the reaction of the liquor. The color is a function of the hydrogen-ion concentration. Thus a series of gambier and quebracho extracts varied in color from a pale straw at a p_H of 3 to a dark red at a p_H of 12. This change in color is completely reversible if the liquors are not long exposed to air. In a similar manner the color of the leather varies directly with the p_H of the liquor used.

Upon exposure to air the liquors darken and this oxidation progresses more rapidly in the liquors having the higher p_H values. In this case the color change is not reversed by lowering the p_H .

CHEMICAL COMBINATION IN CHROME TANNING

Two papers of a series establishing the chemical nature of the combination of chromium with hide substance were presented by Arthur W. Thomas and Margaret W. Kelly, "The Equilibria Between Tetrachrome Collagen and Liquors of Different Chrome Content" and "Adsorption of the Constituents of Chrome Liquor at Various Concentrations After Nine Months' Contact."

Continuing the work which proved the formation of a tetrachrome collagen compound, the authors were able to prepare an octachrome collagen, which would indicate that collagen had a combining weight of 93. It was further possible to prove that the formation of these chromium:collagen compounds is a reversible process, and that chrome tanning is essentially a chemical process.

INFLUENCE OF CERTAIN NEUTRAL SUBSTANCES ON CHROME TANNING

Arthur W. Thomas and S. B. Foster studied the influence of sodium sulphate, sodium chloride and sugar upon the combination of hide substances with chrome. The fact that chrome liquors can be made more basic without precipitation in the presence of certain salts and substances has been explained by the ion hydration theory. This theory does not, however, account for the difference in the action between NaCl and Na_2SO_4 . When the concentration of NaCl is plotted against mg. Cr_2O_3 per g. hide substance, the curve passes through a minimum and then rises to practically the original value. With Na_2SO_4 there is a continuous drop and no recovery.

Experiments with sucrose (which is known to hydrate in solution) showed almost no influence until the solution became quite concentrated. Hence the authors conclude that the initial action of NaCl is due to the formation of an addition compound and that the recovery

is accounted for by the later predominating influence of hydration, while in the case of Na_2SO_4 , which does not hydrate, there is no recovery.

PHYSICAL MIXTURES AND CHEMICAL COMPOUNDS

Dr. Jerome Alexander discussed in a most interesting manner the question of differentiation between physical mixtures and chemical compounds. As in similar problems, there is no sharp line of demarkation and the whole matter rests upon the acceptance of a set of definitions by all interested in the controversy.

EFFECT OF p_H UPON DIFFUSION OF TAN LIQUOR

As ordinarily used in tanning, gambier and quebracho extracts show marked differences in the rate of tanning and of penetration into the hide. In a paper on the "Effect of Change of Acidity Upon the Rate of Diffusion of Tan Liquors Into Gelatin Jelly," John Arthur Wilson and Edwin J. Kern showed that the rate of penetration is a function of hydrogen-ion concentration as well as of the non-tannin content. A sample of gambier penetrated the jelly only at p_H values above 3.0, but a sample of quebracho only at p_H values above 4.7. Above 9.0 the quebracho penetrated more rapidly than the gambier.

CHEMICAL CONSTITUENTS OF SKIN

The chemical constituents of the skin were considered in some detail by Frank L. Seymour-Jones. Of the many compounds present in skin, collagen is the most important. Its chemical structure is still a matter of doubt. The fact that it hydrolyzes to gelatine would seem to indicate that collagen is the anhydride of gelatine. Gelatine when heated yields a substance resembling collagen, but this product does not hydrolyze again to gelatine.

PROPERTIES OF ENZYMES

Joseph Turney Wood, director of Turney Bros., Ltd., of Nottingham, England, contributed a paper on "Properties and Action of Enzymes in Relation to Leather Manufacture." Enzymes apparently differ from inorganic catalysts in that they may start a reaction as well as simply accelerate it.

Enzymes are encountered at many stages in leather manufacture. Those in the soaks and limes are mainly of a proteolytic nature. Many varieties are found in dung bates and commercial bates usually contain pancreatin.

In the drenching process the presence of an amylolytic enzyme is essential. Starches are transformed into dextrine and glucoses, which are subsequently fermented into organic acids.

A CRITICAL STUDY OF BATING

Through the use of the microscope and the hydrogen electrode, John Arthur Wilson and Guido Daub have obtained evidence which proves conclusively that the functions of bating are two—reduction of the skins to a condition of minimum swelling and solution of the elastin. The removal of elastin, which is the primary function of bating, results from the digestive action of the pancreatic enzymes in the bate. Elastin digestion may be followed microscopically by selective staining.

Experiments with pancreatin on strips of limed and un haired calfskin gave the following results:

Elastin removal depends upon the hydrogen-ion concentration of the solution. With a solution containing 0.1 g. pancreatin per liter complete digestion of elastin was effected only when the p_H value of the solution lay

between 7.5 and 8.5—a very narrow margin—but when the concentration was increased to 1 g. per liter the active range was extended to 5.5 to 8.5.

The rate of elastin removal is a function of the concentration of enzyme and of the time of digestion.

Ammonium chloride shows an activating effect in concentrations up to 0.5 g. per liter and a marked inhibitory effect in higher concentrations. It was thought that this latter observation might explain the negative results obtained with several commercial bates. Accordingly samples of commercial bates were dialyzed in order to remove NH_4Cl , earlier experiments having shown that dialysis had no effect upon the activity of pancreatin itself. The results were still negative, however. It was then found that the woody fiber used as a filler in the commercial bates adsorbed the enzyme so strongly that it was unable to function.

From tests made with calfskin, the authors conclude that the value of bating depends entirely upon the properties desired in the finished leather. By applying the principles outlined in this paper, complete scientific control of the bating process is now possible.

ISOELECTRIC POINT OF COLLAGEN

Experiments by Arthur W. Thomas and Margaret W. Kelly indicate that the isoelectric point of collagen is at a hydrogen-ion concentration of 10^{-5} mols per liter.

PHYSIOLOGICAL AND HISTOLOGICAL OBSERVATIONS ON SKINS

A paper on "Physiological and Histological Observations of the Flayed Skin Entering Into the Art of Leather Manufacture," by Alfred Seymour-Jones, was read by his son, Frank L. Seymour-Jones.

The true skin consists of four distinct layers, differing considerably structurally and chemically.

The topmost layer is the grain membrane, which varies considerably in feel and texture with different animals largely according to the type of hair or wool. Just below it lies a thin layer, the cutis minor, vitally important in the manufacture of good leather. Below again is the fatty layer, largely consisting of groups of fat cells, resembling in appearance bunches of grapes. The last layer is the cutis major, which forms the major part of the whole skin. It is composed of white collagen fibers, intertwining in every direction to form a firm and inextensible coat for the body.

In the grain membrane and cutis minor the white fibers are supported by yellow elastic fibers. When, as in bating, the elastic fibers are removed, these two layers become soft and extensible, and the skin "falls."

THE CHEMISTRY OF LIME LIQUORS

W. R. Atkin, instructor in the chemistry of leather manufacture at the University of Leeds, extended the theories of Procter and Wilson and of Loeb to the alkaline swelling of hide in lime liquors. The real reason why such sharpening agents as sodium sulphide and sodium carbonate produce greater swelling than lime alone is that the osmotic pressure which causes swelling is greater for sodium collagenate than for calcium collagenate at the same p_{H} value. The smooth grain of skins unhaired in limes containing arsenic sulphide is due to the fact that calcium collagenate only is formed.

DETERMINATION OF TANNIN

John Arthur Wilson and Edwin J. Kern have succeeded in improving the procedure of their new method of tannin analysis. The revised procedure gives the

same results as the original, but saves a great deal of time and labor and increases the accuracy for unskilled analysts. To make a determination by the revised procedure, it is necessary merely to shake a fixed amount of hide powder with a solution containing a known amount of the soluble matter of the tanning material until all tannin is removed from solution, washing the tanned powder in a special device which prevents the loss of anything but matter in solution, drying the washed powder and weighing it. The increase in weight of the dry hide powder is a measure of the tannin content.¹ All criticism raised against the new method thus far has been refuted.

THROUGH THE TANNERY ON THE INSIDE OF A CALFSKIN

This lecture by John Arthur Wilson consisted of a series of remarkably beautiful sections of calfskin projected upon the screen at a magnification of 2,000 diameters, thus permitting a detailed and critical study of the changes at each stage of the tanning process.

In fleshing, the adipose tissue is cut away just under the flesh layer of elastin fibers. During liming, the substance of the malpighian layer of the epidermis is slowly digested, thus effectively separating the corneous layer of the epidermis and the hairs from the dermis. In bating, the elastin fibers are digested by pancreatic enzymes. After bating, only the grain membrane, collagen fibers, erector pili muscles and a few blood vessels are left. The tannin combines chemically with the collagen fibers. The fat-liquoring process distributes oil uniformly over the surfaces of the fibers. Coloring and the application of finishing materials complete the process of addition.

ASTRINGENCY OF VEGETABLE TANNING EXTRACTS

The reasons for the different degrees of astringency of various vegetable tanning extracts have been long a matter for speculation. The problem has been attacked from a colloid chemical point of view by Arthur W. Thomas and Stuart B. Foster, with the result that astringency has been indicated to be a function of the electrical charge of the tannin particles. The higher the charge the greater is the astringency.

ACTION OF VEGETABLE TANNING MATERIALS

A paper by Arthur W. Thomas and Margaret W. Kelly on "The Time and Concentration Factors in the Combination of Tannin With Hide Substance: 1, Gambier, 2, Quebracho," was the first of a series of studies of the action of vegetable tanning extracts in the formation of leather. It brings out clearly the difference in behavior of an astringent tanning agent and of a mild one. Gambier shows slow regular increase in the amount of tans fixed by hide as the concentration of the extract and the time of reaction are increased. Contrasted to this behavior, quebracho shows a rapid and larger amount of tan fixed than gambier does, accompanied with a sharp maximum followed by an abrupt drop in the fixation.

ELECTION OF OFFICERS

At the business meeting, the following officers were elected: John A. Wilson, chairman; J. S. Rogers, vice-chairman; Arthur W. Thomas, secretary-treasurer; F. Seymour-Jones and C. R. McKee, executive committee. It was voted to hold the next meeting of the division in connection with the 1922 fall meeting of the society.

¹For full details see *J. Ind. Eng. Chem.*, vol. 13, p. 772, September, 1921.

Division of Sugar Chemistry

The Division of Sugar Chemistry met Wednesday and Thursday, C. A. Browne, chairman, and Frederick Bates secretary. A number of the papers presented were of a general interest nature, and others dealt primarily with improvements in analytical methods.

Some Studies on Decolorizing Chars.—Dr. C. E. Coates discussed in a general way the work on decolorizing chars at the Louisiana State University and the Sugar Experiment Station. Many inexpensive raw materials are to be found in Louisiana, and much investigational work has been done on these for the purpose of developing satisfactory methods of manufacture.

The Comparison of Various Blacks Upon the American Market.—C. E. G. Porst and J. M. Krno in their paper on the comparison of various blacks upon the American market stated that the efficiency of various carbons in decolorizing glucose liquors was determined by comparative laboratory tests in which not only the initial but also the total decolorizing power was considered. They also studied the relationship between fineness of mesh and decolorizing efficiency.

Adsorption Isotherms of Some Decolorizing Carbons.—F. W. Zerban and S. Byall using various commercial carbons and blackstrap molasses, made experiments to determine whether decolorization follows the adsorption formula of Freundlich. A Hess-Ives tintometer was used, and Mead's units for expressing the color. Different curves were obtained for different concentrations of molasses.

Decolorizing Carbons and an Inquiry Into Fundamentals of Sugar Colorimetry.—H. H. Peters reported the results of his studies on the decolorizing efficiency of several carbons. The author used optically clear filtrates for the determination of remaining color. It was pointed out in the discussion that there is need of an absolute method for measuring color, but very great difficulty in developing such a method.

Mechanical Clarification of Cane Juice Liquors.—A. S. Elsenbast spoke about the growing use of filter aids, such as Filter-Cel, and the results obtained in factory practice in Louisiana during last year's grinding season were given in considerable detail.

Rôle of Fermentation in the Deterioration of Cane Sugar Products.—C. A. Browne, C. A. Gamble, G. H. Hardin and M. H. Wiley have studied the rôle of fermentation in the deterioration of cane sugar products. Analyses were made of molasses, soft refined sugar and various grades of raw sugar. The average moisture content and percentage of invert sugar were higher for the deteriorated sugars. Slow inversion, with subsequent destruction of invert sugar by the micro-organisms associated with deterioration is apparently the explanation. The best remedy is believed to be more thorough drying.

Purification and Concentration of Enzyme Solutions for the Rapid Analysis of Sugars by Enzymotic Hydrolysis.—A method for preparing highly active enzyme solutions of great stability was described by F. W. Reynolds. The process may readily be adapted to the manufacture of enzymes on a large scale, and therefore encourages the more widespread use of the enzyme method of analysis.

Precipitation of Gum From Beet Molasses.—H. S. Paine and C. F. Walton, Jr., described a small-scale process developed primarily for the purpose of preparing sufficient beet gum to permit a study of its

properties. The difficulty in eliminating this non-sugar economically on a factory scale, either by precipitation or by adsorption by decolorizing carbon, was strongly indicated.

Chemical Properties of the Gum From Cane Affected by Cobb's Gummy Disease and Its Influence in the Sugar-House.—C. F. Walton, Jr., and O. S. Keener reported their observations in Porto Rico. They stated that the real remedy without question would seem to be the eradication of the disease in the field. A purified solution of the gum was found to be optically active, but since it was completely precipitated by basic lead acetate, as in the usual method of analysis, the inference was drawn that the presence of the gum in cane juice does not interfere with the laboratory analyses.

OFFICERS ELECTED

The following officers were proposed by the nominating committee and unanimously elected by vote of the members present: Chairman, S. J. Osborne; vice-chairman, F. W. Zerban; secretary and treasurer, F. J. Bates; executive committee: C. A. Browne, C. E. Coates; W. D. Horne, W. B. Newkirk, H. S. Paine, H. E. Zitkowski. A rising vote of thanks was given Dr. C. A. Browne, the retiring chairman, for his service to the section.

Section of Cellulose Chemistry

The meetings of the Section of Cellulose Chemistry were held Wednesday and Thursday, Sept. 7 and 8, under the chairmanship of Harold Hibbert, with G. J. Esselen, Jr., as secretary. Among the papers presented were the following:

A preliminary communication by Walter Russell and Louis E. Wise on "Acetolysis of Wood Cellulose" indicated a mode of attack on the question of the "normal cellulose" content of wood pulp and led to a discussion as to the reason why nitrated pulp cannot be used for the manufacture of celluloid. It was apparent that a closer definition of so-called "normal cellulose" is necessary, and it is expected that the committee appointed to supervise the manufacture of pure cellulose for purposes of scientific research will give attention to the matter.

"The Constitution of Cellulose" was discussed by Harold Hibbert in the light of the recent work of Karrer and Widmer, Freudenberg, Irvine and Monier-Williams, the evidence of the two former investigators indicating the probable incorrectness of Hess' formula. An explanation was given, in the light of the Hibbert formula, of the connection between cellulose, cellobiose and dextrose in their various modes of transformation into one another, and the forecast made of the probable synthesis by workers in this field of a wide variety of new cellulose derivatives of industrial importance.

The paper by Alfred Tingle on "The Alleged Adsorption of Alumina From Solutions of Aluminum Sulphate by Cellulose" occasioned an animated discussion, most of which was apparently opposed to the negative view taken by the author, so that the details of the paper will be awaited with interest. One point developed in the discussion was the admission that no satisfactory titration method existed for the determination of the basic aluminum hydroxide in aluminum sulphate, a point which is to be investigated by those interested.

The rôle of cellulose in plant life was reviewed by R. W. Thatcher, two points being strongly emphasized: On the one hand the absence of cellulose splitting

enzymes in the early stages of plant growth and the other that cellulose serves one function only—namely, that of a structure-forming material.

The determination of methoxyl groups in wood-distillation products by L. F. Hawley and Subramanya Aiyar was a continuation of the Forest Products Laboratory investigation on the action of small amounts of sodium carbonate in increasing the yield of methanol in wood distillation. It is no secret that Hawley's process is now being tried out on the commercial scale and with promise of success.

The technique of preparing viscose solutions for laboratory experiments was given by W. O. Mitscherling, while some new light was thrown by H. E. Wilkie on the commercial possibilities of ethyl acetate as a solvent for nitrocellulose and cellulose acetate.

The question of the most suitable type of monograph on cellulose chemistry led to considerable discussion following the review contributed by Dr. Louis E. Wise. The chairman was requested to forward Dr. Wise's paper to Dr. John Johnston as representing in general the views of the section.

The committee on viscosity standardization reported favorable replies from fifteen out of eighteen different manufacturers. They recommended the adoption of the "dropping-ball procedure," the details to be worked out by the committee with facilities offered by the du Pont company.

The committee on preparation of standard cellulose suggested that Dr. Bjarne Johnsen be asked to have his method for cotton purification printed in one of the technical journals, reprints of which are then to be submitted to the members of the section for criticism and comments.

Both reports were adopted unanimously.

In view of the different analytical methods at present in use in cellulose investigations, a committee was appointed to report on the best available methods.

Section of Petroleum Chemistry

The meetings of the Section of Petroleum Chemistry were held Wednesday, Thursday and Friday, Sept. 7, 8, 9, under the chairmanship of T. G. Debridge, and with W. A. Gruse secretary. Of the sixteen papers presented seven constituted a symposium on emulsification problems in the petroleum industry.

No papers were read Wednesday, as all the time was taken up by discussions concerning just what the section could do to bring about work on the fields of research.

Dr. Van H. Manning, director of research for the American Petroleum Institute, took part in this discussion, pointing out the necessity for educational work and standardization of testing methods.

A number of subjects were listed, and it was decided that an effort be made to bring together the academic and the technical research men in such a way that university research work on the physics and chemistry of petroleum might be stimulated. Dr. B. T. Brooks pointed out the absence in this country of the benevolent activities of such a firm as the Nobel Bros. Co. in pre-war Russia, which subsidized a great deal of purely academic work and helped put Russian petroleum chemistry in the high position it occupied before the collapse of that country.

On Thursday morning Peter Kerr, of London, one of the Society of Chemical Industry visitors, presented a letter of greeting to the Petroleum Section from Presi-

dent J. S. S. Brame of the Institution of Petroleum Technologists. Mr. Kerr spoke briefly and was an interested participant in the sessions.

The program opened with a paper by E. M. Johansen on iodine and bromine values of petroleum products. Mr. Johansen presented a large amount of very valuable work on this puzzling question and recommended a new reagent.

Thomas Midgley, Jr., presented some observations on the polymerization of amylene. As cracked gasolines are more plentiful in our motor fuels and the removal of the gum-forming constituents therein more important, it is clear that we need to know more about the chemistry of the unsaturated compounds from which the gums are formed.

R. E. Wilson and D. P. Barnard, of the Massachusetts Institute of Technology, supplemented papers presented to the section at Rochester by one on total heats of motor fuels.

SYMPOSIUM ON EMULSIFICATION PROBLEMS IN THE PETROLEUM INDUSTRY

The symposium on emulsification problems in the petroleum industry drew much attention. The material which the oil producer knows as "B.S.," or bottom settlings, may contain from 20 to 80 per cent good oil, and many new fields, such as the El Dorado, in Arkansas, produce much of this material; in addition, it collects at the bottom of nearly every storage tank in the mid-continent and other Western fields.

Dr. L. W. Parsons presented a detailed study of laboratory emulsions made with Nujol and mono- and di-valent soaps as emulsifiers; the inversion of phases was studied and a definite concentration found for the salting out of oil-in-water emulsions.

Prof. T. R. Briggs, of Cornell University, discussed emulsions with finely-divided solids. The author showed antagonisms between different finely-divided solids paralleling those between the different types of soaps.

Dr. J. L. Sherrick's paper presented the idea that the active agent in making oil-field emulsions is a film of finely-divided silt or clay, carrying adsorbed asphaltic matter. There was an interesting correspondence between this paper and that of Dr. Briggs.

E. E. Ayers, Jr., discussed the common characteristics of petroleum emulsions. He remarked on the rather striking uniformity of oil-field emulsions, told why it is a mistake to try to break up an emulsion by heating with a closed steam coil, and touched on such new topics as resolution of emulsion by filtration through media which are selectively wetted.

Practical methods for resolving emulsions as now used in the oil fields were presented in papers by R. R. Matthews and P. A. Crosby and by Dr. Sidney Born. The former paper was confined to a particular kind of chemical process, while the latter covered briefly the electrical, chemical and thermal methods, as well as the use of the supercentrifuge.

In the discussion following the symposium, H. C. Eddy gave a detailed account of the Cottrell process as commercialized, and Dr. F. W. Lane explained recent developments in low-voltage resolution.

The last action of the section before adjournment was to vote that the question of making the section a division as soon as possible be taken up; it was generally felt that this action was justified by the continued interest shown in the meetings of the section and its rapid growth since its formation in the spring.

Welding; Particularly Hammer Welding

Brief Discussion of Various Modern Methods of Welding, Indicating Advantages and Limitations of Each, and the Field for Hammer Welding Heavy Pressure Vessels—
Operations Necessary for Hammer Welding Steel Sheets

By ERNEST EDGAR THUM

METALS can be joined together in many ways. Even after excluding the various mechanical splices, riveted, bolted or keyed together, two pieces of like or unlike metals may be joined by several methods so that their substance is continuous.

A few years ago "welding" meant blacksmithing; to city dwellers with broken automobiles it now means some mysterious manipulations with a harmless looking torch or a sputtering electric arc. Soldering and brazing are less like these operations, but they also join metals into a continuous substance. Welding, therefore, is rather a broad term if it is to include all methods of making metals cohere.

MOLECULAR COHESION NECESSARY FOR WELDING

High heat is not always essential. An autogeneous joint can be made between two pieces of gold or lead by strongly pressing them together at room temperature. In some cases pressure is not needed if the temperature is high enough—notably in thermit or other methods of "fusion welding." Even tool steel may weld to a certain extent by heating freshly fractured surfaces in contact after wrapping the joint in platinum foil and heating to a low red. The main thing seems to be to get intimate contact—molecular contact in fact—between the two sides of the joint.

When such a union is examined even under the microscope, it is very difficult to determine where the one piece stops and the other starts; there is a certain amount of actual interpenetration in all good welds. In fact the former junction surface is now crossed by metallic crystals, portions of which came from one piece of metal and portions of the same crystals from the other. Hence follows Stead's law of welding: "Unless the crystals become common to the two pieces there is no welding."

Heat is undoubtedly the handiest method of securing such molecular interpenetration. As noted above, many modern methods use heat alone, actually melting the metal at the joint, just as in soldering. However, heating to high temperatures is accompanied by two major difficulties: Even the best and purest metals are subject to rapid and profound physical changes at elevated temperatures; furthermore their chemical activity is enormously increased. The former rearranges the crystalline structure of the underlying layers of metal with an accompanying change in strength and ductility. The latter difficulty is responsible for rapid oxidation of some major component of the alloy being welded, and the resulting oxide must be got rid of in some manner or the joint will be unreliable.

SOLDERING AND BRAZING

Such inherent disadvantages of high temperature may be dodged by soldering and brazing.¹ Here the cleaned surface is covered with a thin film of fusible solder so selected as to form low-melting alloys with the underlying piece at the moderate temperature employed (Fig. 1). Thus a true weld is formed between piece and solder. Two pieces, prepared in the same way, are then held together, merely warmed to the melting point of the solder, and presto, they are joined.

Unfortunately, all low-melting alloys now available for soldering are deficient in strength. The joint is by no means as reliable as the pieces joined. It has an entirely different chemical and metallurgical nature, and can never approach the welder's ideal—to produce a joint which cannot be located because it is exactly like the pieces joined. In avoiding the dangers of oxidation, even greater chemical heterogeneity is produced.

CLASSIFICATION

A workable compromise between high heat and no pressure and no heat and high pressure has been used since prehistoric times by the worker in wrought iron.

FIG. 1.

Section across soldered joint of two pieces of copper. Etched with ammonia. The solution of the tin in the copper is indicated by the light unattacked border along each side of the joint. Magnified 100 diameters.

¹Groets, "Metallography and Heat-Treatment of Metals Used in Aeroplane Construction," CHEM. & MET. ENG., vol. 19, pp. 317, 583.

Only in comparatively recent years, however, have inventors provided other methods of producing heat than an open fire; these have been utilized in new welding methods. Excluding soldering and brazing, the following is a somewhat loose classification of the important ways of making coherent metallic joints in iron and steel, and their principal uses.

Class	Principal Utility
Electric Resistance Welding	
(1) Butt welding	Bars and wires
(2) Spot welding	Lap seams
Fusion Welding	
(1) By electric arc	} Butt seams
(2) By gas flame	
(3) By thermit	
	Heavy castings, shafting and forgings
Forge Welding	
(1) In smithy	Bar iron and steel
(2) By special machinery	Heavy tanks and pipe

ELECTRIC-RESISTANCE WELDING

Electric-resistance welding utilizes the fact that even though good conductors of electricity, metals offer some resistance to its flow. In overcoming this resistance heat is generated. If now a sufficient electric current can be concentrated and forced to cross a joint to be welded, the joint can be heated to a temperature where moderate pressure will cause a true weld.² Practically all metals and a great many alloys can be welded by this process, as well as combinations such as brass to copper, silver or gold, mild steel to tool steel, steel to platinum. It is not suited for cast iron. Metals of relatively low melting point, zinc, lead, tin and aluminum, may be welded by taking the proper precautions; even magnesium has been welded.

As noted in the classification, two principal methods of resistance welding are in common use. The usual butt-welder consists of a pair of heavy copper vises

FIG. 2. BUTT WELDING MACHINE CAPABLE OF WELDING STEEL PIECES UP TO 0.5 SQ. IN. CROSS-SECTIONAL AREA

(Fig. 2), one fixed and the other on a slide so it can be thrust toward the other at the moment of welding. The two bars to be joined are shown clamped (abutting about midway between vises) and serve as part of the secondary circuit of an alternating current transformer built into the base of the machine. A small amount of current is drawn from the supply line,

transformed into low-voltage, high-amperage current flowing through the iron bars, heating them to the correct temperature. Pressure applied by the hand lever through the movable vise then forces the hot plastic metal into molecular contact, upsetting it a little into a rounded bulge. If the pressure and current are held a longer time some white-hot metal is extruded as a perpendicular fin. Cooling takes place immediately after the current is shut off. The weld is usually annealed by a low current, and excess metal pressed down or the flash cut off.

This is in every respect the best way to join rods or bars end to end, especially in repetitive work on material less than 2 in. diameter. Fencing and cables can be made of endless wires, by merely butt-welding

FIG. 3. CRATER FORMED BY SPOT WELDER WHEN JOINING TWO STEEL SHEETS

successive coils. Forged ends or steel of special analysis can be welded to stock rods. Other manufacturing processes readily suggest themselves.

It is necessary to anneal these welds if they are to withstand shock, since the metal at the joint is heated intensely in the few seconds the current is on, and then cooled very quickly (in fact "quenched") by the cold underlying metal.

This means that the bar at the weld and for perhaps half a diameter on either side is in a hardened condition; its strength and brittleness increase with the carbon content of the stock. The heat is extremely short and under close control, however, and there is no excuse for extreme grain growth, "burnt" steel, slag inclusions or blow-holes. Unfortunately, the operation is in the open air, and high-carbon steel will lose up to one-half its carbon content throughout a thin layer at the weld. It is not necessary to dilate upon the harmful effect of this decarburization, despite any subsequent heat-treatment.

SPOT AND PERCUSSIVE WELDING

Spot welding uses the same electrical principles to weld small areas and to replace rivets when joining sheets or shapes. Imagine a yoke riveter with "snap" and "dolly" replaced by thick copper pencils, and with correct connections for high amperage electrical currents, and you have the essentials of a spot riveter. Two or more pieces are assembled and squeezed between these copper terminals and sufficient current passed across the joint to weld the adjacent surfaces over a small area, somewhat larger than that of an

appropriate rivet (Fig. 3). Pressure and current are then released, and the work shifted for another "spot."

It is rather strange that so excellent a process has not been put into as wide use in structural and plate work as it has in the manufacture of racks and gratings. Plain pieces of plates and angles can be stitched together without the labor of templet making, laying out, punching, reaming and rivet heating. The method makes a weld over a small round area which approaches the ideal; if the plates are clean there is very little decarburization, no blow-holes or slag, while the hardening caused by rapid cooling of the spot by surrounding cold metal is of minor moment in a connection between mild steel pieces.

The electro-percussion method depends upon sending a heavy current from a highly charged condenser through the points of contact of the metals to be welded at the instant they touch as they are brought together with more or less impact. The intense heat is developed so quickly that it is confined to the surfaces as they fuse together. It is used a great deal for joining wires and can be employed for practically all metals and alloys as well as for combinations. One of its chief uses at present is the uniting of copper and aluminum wires, which can be done in no other way with uniformly satisfactory results. Metals of widely varying melting points—for example, tin and platinum—can be welded by this means. It also finds many applications in the jewelry trade. The method has not yet been developed for anything but small pieces.

FUSION WELDING BY ELECTRIC ARC

Fusion welding, as the words imply, utilizes a much higher temperature than will produce the pasty state needed for resistance welding. The material at the joint is actually melted. Thus it is like soldering. It is further like soldering in that a space between the pieces is filled with fresh metal, seldom of the exact composition as that which it joins.

Either an electric arc or certain gas flames may be used to produce enough heat for local fusion. Such welds are usually made by filling up a notch or corner between the two pieces with molten steel, added a little at a time.

If the work is grounded and an arc struck from a

steel wire, a small spot is raised to incandescence and builds up liquid metal acquired from the electrode. Metal is transferred through the arc, partly as a true vapor, partly as hot particles driven off by explosive expansion of gas occluded in the wire, but mostly as larger droplets, melted from the end. Such a deposit is gradually built up in layers, until the joint is filled from end to end. In view of the fact that the arc is a region of intensely hot gases (oxygen, nitrogen and iron) mounting up to 3,500 deg. C. or more, it is not surprising that the deposited metal will have lost much of its carbon, silicon and manganese and acquired oxygen and nitrogen. As ordinarily made at the present time it is in fact a low-carbon casting (Fig. 4) made and cast continuously under unfavorable conditions, containing many blow-holes and unusual compounds, whose specific effect is not as yet thoroughly explained (Fig. 8). Rawdon and others at the Bureau of Standards have cut test-bars from heavy deposits of weld metal³ made from low-carbon iron and steel welding wires and find that while possessing fair ultimate strength (50,000 lb. per sq.in.) it is likely to be quite deficient in ductility.

Great variation existed in these tests; the best ultimate strength was 54,500 lb. per sq.in., the highest yield point 36,250, the best elongation 15.0 per cent and the best reduction in area 23.0 per cent. It seems fair to conclude, therefore, that perfection of operating methods and increase in operator's skill will result in much better fusion welds than have been made in the past. The use of proper alloy steels as welding wires is a line of development which as yet has been hardly touched, but holds out promise of successfully making weld metal of high strength and toughness.

Unfortunately there is little opportunity for working or heat-treating these welds—they are usually performed on fixed objects, or as emergency repairs and must ordinarily be used as made. Actual fusion of the original metal at the weld causes other metal in the immediate vicinity to be overheated, resulting in a coarsening of the grain with its characteristic ferrite envelopes (Fig. 5). This state of affairs, accompanied

³See Rawdon, "Physical Properties of Arc-Fused Steel," CHEM. & MET. ENG., vol. 23, p. 677 (Oct. 6, 1920). Also Bureau of Standards Technologic Paper 179.

FIG. 8. ELECTRIC ARC WELD IN 1/4-IN. BAR STEEL.
× 600. (MILLER)

as it is by oxygen penetration, reduces the ductility and resistance to shock, and induces intergranular fracture; consequently if a well-made weld is tested to destruction it would probably fail in the underlying layers, rather than in the weld.⁴ Such physical defects, if not too pronounced, can be cured by proper heat-treatment—in fact, they are partly corrected in a crude and uncontrolled way by the heat of successive passages of the arc, a factor difficult to appraise (Fig. 6). Extensive and accurate heat-treatment probably combined with mechanical work would be necessary to correct the major defects of a fusion weld.

On account of the nature of the radiation from the arc, it is necessary that the operator be carefully protected. Simply shielding the eyes is insufficient, the head and hands must be protected from the ultraviolet rays which form a large proportion of the radia-

FIG. 9. PIPE JOINT BEING MADE BY GAS WELDING.
(OXWELD ACETYLENE CO.)

tion emitted by the arc. A special glass window which not only shields the eyes from the heat and intense light but also cuts out the ultraviolet (invisible rays) is a necessity.

Many of the same difficulties beset welding with a

gas flame, commonly acetylene burning in pure oxygen. The temperatures are 1,000 deg. less,⁵ but still far above the melting point of iron or steel, and in a range where oxidation is rapid and excessive. Metal is filled into the notch by melting off the end of a wire, held close to the work (Fig. 9). Fortunately the liquid iron is somewhat protected from atmospheric oxygen and nitrogen by a rather thick "envelope" flame. It is commonly known that a typical oxyacetylene torch produces an inner cone of white-hot carbon burning to CO. Outside this is the envelope of burning CO and H, which spreads out and heats the underlying metal for some distance on all sides. Due to this extensive spread, gas welding overheats the work more extensively and is perhaps less suitable for thick plates or structures which are rigid and may be buckled by

FIG. 10. WELD MADE IN MILD STEEL, ETCHED WITH
AMMONIUM PERSULPHATE. FULL SIZE

the heat than the electric arc, but it is more suitable for cast-iron⁶ or thin steel sheets. But even at best the weld metal is a casting, it contains more or less oxide, and the underlying grain is severely coarsened. Figs. 4 to 7 are typical of the microstructure of all untreated fusion welds; they comprise a central portion of deposited metal, bordered by original metal reheated to various degrees. All metal heated beyond the critical temperature has recrystallized, resulting first in a refinement (Fig. 6) or coarsening (Fig. 5) as the heat goes up. In gas-welded plates the distance from the edge of the filled-in metal to the unaltered stock will equal four times the thickness of the plate, while such a zone is confined to 1/8 in. in an electric weld.

Figure 10 is a macrograph of a weld made at the Union Carbide and Carbon Research Laboratories in mild steel with a low carbon filler rod, later cut, polished and etched with ammonium persulphate. Disregarding the long "ghost," the clean even line at the weld junction, and the solid, homogeneous nature of the filled metal shows what can be done by a skilled operator. Fig. 11 shows test pieces bent back upon themselves, with the bottom of the V-notch inside, and Fig. 12 is the microstructure at the original edge of the plate.

Many of the remarks made under electric arc welding about variation in strength of welds and weld metal depending upon the operator's skill apply with equal force to variation in the quality of gas welds. The Union Carbide and Carbon Research Laboratories have made many tests on bars cut from deposited metal, the welding being done under a wide variety of conditions, and find that the resulting deposit possesses quite uniform physical properties when made by reliable workmen. Typical results of metal de-

⁴Rawdon reports tests on ten superior welds averaging an ultimate strength of 55,650 lb. and elongation of 7.5 per cent. The best broke at 59,470 lb. per sq.in. and the best elongation was 14 per cent. These joints were in ship plates having an ultimate strength of 68,000 lb. per sq.in. and elongation of 22 per cent.

⁵Bureau of Standards Letter Circular VIII-8 gives the temperature of the oxyacetylene flame as 2,400 deg. C., and the oxyhydrogen flame as 2,000 deg. C.

⁶Cast iron must be preheated.

FIG. 11. COLD BEND IN PLATES WELDED BY OXYACETYLENE FLAME

posited from well-known filling rods follow; each figure representing the average of five:

Metal	Ultimate Strength
No. 1 Filler.....	55,600 lb. per sq.in.
No. 2 Filler.....	59,340 lb. per sq.in.
No. 3 Filler.....	64,500 lb. per sq.in.

Either the arc or flame weld is very good for repairs on parts enduring static loads which have a considerable excess of strength or for building up worn or missing metal. An oxyacetylene outfit especially is portable and if necessary may be taken to the work rather than *vice versa*, and with another torch supplying a separate stream of oxygen can be used for cutting metals as well, thus making it a most useful shop tool. It is also used for welding copper and its alloys, aluminum and its alloys, malleable and cast iron. Under the name "lead burning" it is used for welding lead pipe, sheet lead, etc. It is only necessary to protect the eyes with dark glasses, as shown in Fig. 9, owing to the lower actinic value of the flame as compared to the radiations from an arc.

As is well known, much work was done during the war to determine whether fusion welding could be used in hulls to replace riveting, but it has not found great favor among shipbuilders or boiler makers, except to fix small fittings, probably due to the fact that so much depends upon the skill and care of the workman, and the difficulty of inspection. Besides repair work it is

FIG. 12. MICROSTRUCTURE OF FILLED METAL NEAR ORIGINAL EDGE OF PLATE, ETCHED WITH 5 PER CENT. HNO_3 IN ALCOHOL. $\times 100$

largely used for manufacturing low-pressure tanks and barrels, structural tubing and for sheet or seam welding wherever met with.

WELDING WITH THERMIT

Fusion welding may also be done with thermit. A thermit crucible is nothing more than a small furnace producing steel by the reaction between finely divided aluminum and iron ore,

The aluminum burns in the oxygen from the ore, producing sufficient heat to liquefy the whole mass, which is then tapped directly into a sand mold formed around the broken casting (Fig. 13). The broken ends have previously been heated by a torch and at the moment when the white hot liquid metal arrives are themselves at a red heat, and actual melting takes place for a slight depth.

Since the added metal may be alloyed or carbonized to suit, and molding and casting are done by exactly the same principles as those underlying steel founding,

FIG. 13. ASSEMBLY OF EQUIPMENT FOR REPLACING BROKEN TOOTH ON A HEAVY PINION BY THERMIT WELDING

it follows that a well-made thermit weld may have the same composition and structure as the steel casting it joins. Care, of course, must be exercised to prevent any slag contamination, or oxidation or carbonizing at the solid ends during preheating. There will also be a grain refinement in any adjacent metal which has been heated above the critical temperature; but this is an improvement rather than a detriment.

Without doubt, thermit welding is the best method for repairing heavy steel castings. It is also the only practicable method for extremely heavy forgings. Its use here presents the obvious deficiency that two forged pieces are joined by a casting. Even though the chemical composition may be the same, it would seldom be possible to subject the joint to the work and heat-treatment necessary to make the repaired unit a homogeneous structure. Such an operation would probably cost as much and require more time than a new piece; consequently thermit repairs on forgings are best adapted for quick repairs on busy machinery whose broken part if a forging ordinarily works under a considerable margin of safety.

It may be inferred that these new styles of welding have not seriously encroached upon the wide range of hand work done in soft steel and iron by the expert blacksmith. With perhaps the single exception of butt welders, they have extended the usefulness of the welding operation to fields where it had seldom been employed. Thus, spot welding and fusion welding in their largest use replace riveting in plate work, while thermit negotiates tasks far too heavy for the ordinary forge shop. They all do work or join metals which would not be attempted by the blacksmith; on the other hand nearly all of them have drawbacks which limit their usefulness. For instance, butt welding is accompanied by deep-seated decarburization, arc or gas welding sticks on tabs of metal quite likely to be "gassy" and deficient in ductility. On the other hand, forge welding is limited to wrought iron or low-carbon steels. None of them have solved the problem of producing a safe, "seamless" pressure vessel, or one often subjected to wide variations in temperature or stress. A riveted tank working under those conditions will not remain tight even by most expert riveting and caulking. Instances are autoclaves, drums for cracking gasoline, and boxes for annealing light sheets. If some thoroughly dependable method for making such welded seams could be devised, undoubtedly a wide variety of pressure vessels, boilers and pipe will eventually be made in that manner.

WELDING BY MACHINERY

Consequently for some years, engineers at various places have been working on the problem of translating the art of the blacksmith to the modern factory with its labor-saving machinery of high power. There seemed to be no inherent obstacle preventing a 100 per cent joint in wrought iron or mild steel. Wrought iron when originally taken from the puddling furnace is a sponge of metal, yet it welds easily in the rolling mill or under a hammer into a tough, strong bar, composed of elongated strings of crystals of nearly pure iron together with a certain quantity of slag drawn out into threads. Yet this welded material has nearly the same tensile properties as open-hearth iron, cast liquid from the furnace and rolled exactly like steel products. In other words, particles of ferrite can be properly welded into a bar as strong as one of nearly pure ferrite, cast and worked from the ingot. Why, then, should not a welded joint develop an efficiency of 100 per cent?

One variety of thoroughly reliable machine-welding has been known for nearly a century and practiced in the manufacture of pipe or tubes, first of wrought iron and later of low-carbon steel. It is well known that small pipe is made by pulling white-hot "skelp" (plates of the correct width and thickness) through a die or bell having an opening of the exact size of the outside of the pipe, the bell at the same time forming the tube and pressing the edges into welding contact. Pipes larger than 3 in. are lap-welded. The skelp is scarfed on the edges, heated and bent into the approximate cylinder, reheated, and rolled at a welding temperature over a mandrel, and finally straightened before becoming cold. Such methods serve to make pipe up to 30 in. in diameter. These longitudinal seams are not as strong as the metal comprising the rest of the pipe wall, as shown in Table I. However, the characteristics of welded pipe as manufactured in modern plants are well known to the engineering profession, and they are as

dependable as any other metallurgical product. One in five burst lap-welded tubes will be found to have failed by some defect in the pipe wall, rather than in the joint.

This digression is warranted as an indication that it is not unreasonable to extend further the principles of "fire welding" to hitherto untouched fields. Of course not all metals or even iron alloys can be welded by forging. Weldable metal must lose its brittleness, becoming soft and "sticky" some little distance below the melting point, or even the "burning" point—that temperature where some constituent is rapidly oxidized. Wrought iron is an excellent material for welding because it becomes soft (in this sense) 200 deg. below its melting point, and it may readily be heated to 1,400 deg. C.—100 deg. below its melting point—without danger of burning. This safety is in turn due to the fact that the metallic part of wrought iron is pure metal, and it contains only a minute amount of fusible eutectics which allow penetration of oxygen at high temperature, with consequent damage resulting in intercrystalline weakness. Furthermore, the contained slag undoubtedly melts and flows over the exposed metal surfaces, thus protecting them from oxidation, and dissolving any oxide which might previously have been formed. It is well known, for instance, that the welder, when making wrought-iron pipe, judges the correct temperature by observing when the white hot skelp becomes wholly covered with a glassy sheen—gets "greasy," as he says. This indication occurs at a definite temperature, and is quite apparent even to the unpracticed eye.

TABLE I. ULTIMATE STRENGTH OF PIPE WELDS

	— Steel Pipe ⁷ —		— Wrought Iron — Pipe	
	Butt- Welded Lb. per Sq. In.	Lap- Welded Lb. per Sq. In.	Butt- Welded Lb. per Sq. In.	Lap- Welded Lb. per Sq. In.
Average strength of metal.....	57,000	57,000		
Average strength of weld.....	41,600	51,700	29,050	29,460
Maximum strength.....	58,160	59,540		
Minimum strength.....	33,030	47,030		
	per cent	per cent		
Average efficiency of joint.....	73	92		

Ferrite itself oxidizes very easily and at low temperatures. Beginning at 200 deg. C. occur the iridescent "temper colors" known to the forge shop, really due to thin films of oxide. Oxide is brittle and unweldable at all temperatures and melts at 1560 deg. C., which is some 30 degrees above the melting point of pure iron. Therefore it can not be squeezed out of a hot weld unless fluxed into a fusible slag. Nor can it be left in the joint with impunity. Fortunately, low-carbon steel especially made for pipe welding acts very much like wrought iron as it approaches the welding temperature. It contains enough silicon, or picks up enough silica, alumina and lime from the furnace bottom, to lower the melting point of the scale to below the "burning" temperature. The pipe maker in this case also watches for the time when the skelp becomes "greasy," and immediately draws it into the welding die.

It is more than a coincidence that wrought iron, the smith's universal metal, is the metal which welds best and easiest. Wrought iron has always been made in crude furnaces, from which it is drawn as a spongy mass. Despite exposure to the air, it welds readily into a bar, tough and strong regardless of crude manipulation. Wrought iron is a weldable material from the first; if it were not capable of being welded

⁷R. T. Stewart, "Strength of Steel Tubes, Pipes and Cylinders Under Internal Fluid Pressure," *Journal, American Society of Mechanical Engineers*, April, 1912.

FIG. 14. WELDING HEAVY WROUGHT-IRON CHAIN IN DOLLY DIES AT THE BOSTON NAVY YARD

by the smith, it would never have been more than a useless lump, a conglomerate of iron and slag particles, a thing to be avoided rather than produced.

Soft steel is less easily welded, except when occasionally made with this end in view, but most of the so-called "iron" on the market in bars and pipe is really steel. It may not be heated so high—with increasing carbon the forging temperature is lowered, the pasty stage narrowed and danger of burning (by melting of some fusible segregates) increased. A high-carbon steel will "burn" before it loses its brittleness and before the scale can be fluxed into a fluid covering, and consequently is unweldable by this slow-heating process.

EFFICIENCY OF FORGE WELDING

In order to get an idea of the strength of commercial welds, Bauschinger's series of tests may be noted. He examined some carefully made welds, with the result that hand-forged welds of wrought iron gave an average efficiency of 87.9 per cent; when forged under the steam hammer they averaged 91 per cent of the strength of the original bar. With soft steel the hand-forged welds had an average efficiency of 84 per cent, while the power-forged welds developed 97.2 per cent. Hand-made welds have been variously reported to possess from 30 to 100 per cent of the strength of the parts joined, a great variation depending upon the skill of the smith, his methods and the difficulties of the job. Such great variation is doubtless responsible for the conservative attitude of various boiler codes toward welded joints. For instance, the American Society of Mechanical Engineers' code allows no more than 28,500 lb. per sq.in. as ultimate strength in a wrought joint in plate steel having a minimum strength of 45,000 lb. per sq.in., an efficiency of no more than 63 per cent. Welded pressure vessels are now regularly made which are

guaranteed to have 90 per cent joints, and no difficulty is experienced in getting insurance underwriters to accept them at that rating. Tests to be quoted in a later article also show that 90 per cent is a conservative value for longitudinal seams in large piping.

That very high-grade work can be regularly done even with simple equipment is evident from the fact that hand-welded chain is universally regarded as being one of our most dependable tools. The problem is therefore to study the technique of hand-forging and to develop machinery which will prevent or minimize those occurrences which produce weak or variable joints.

A smith prepares his weld by upsetting or scarfing the pieces to be joined. He provides extra section so that it can be thoroughly hammered and yet not be undersize. He also shapes his pieces to be joined so that first contact during forging is over a relatively small area; the pieces are then gradually forced together, squeezing any fluxed oxide or slag out of the joint. He heats the parts in a clean fire, making sure that the metal is clearly heated through, yet without burning on the edges. When a proper heat is had, he dashes on a certain amount of sand, places the pieces one against the other on the anvil, holds them firmly in place and quickly and vigorously hammers them together, continuing the work on the weld and on the hot regions abutting until the metal has passed through the recalcence temperature, when danger of grain growth no longer exists.

A mechanical welding operation, simulating hand-forging, must therefore heat the pieces rapidly to the correct temperature without oxidation, and quickly hammer the hot metal together, continuing the work through recalcence. Transfer of tools or heated metal must be very rapid. The work must be firmly held. Finally the completed article must be bodily put into an annealing furnace, to relieve internal strains and refine the grain.

It must remove as many as possible of those empirical conditions which are so difficult to control in hand-work and which make it remarkable that so many welds are good, not that a few are very bad. A weld may appear under certain test conditions to be actually stronger than the welded part, but that is because the adjacent parts have been badly overheated and not hammered, or because the joint has been carburized by the fire. Both of these conditions are due to negligence, and cause an amazing paradox—the less skillfully the welding is done the better the weld may appear to be.⁹

CHAIN WELDING

A correct method was worked out and introduced in the Boston Navy Yard in 1914 for hammer welding the heavy chain cables used in the U. S. Navy.⁹ Briefly the process is as follows: The bars of double refined wrought iron, up to 3½ in. diameter, are sheared to the length necessary for one link, one end heated in an oil-fired muffle, then taken to a press where it is upset and scarfed. The other end is then heated, upset and scarfed in the same manner. The whole bar is then heated, and bent into the shape of a link by a special bending machine, threaded into the end of the growing chain, and the scarfs closed under a heavy steam ham-

⁹"The Welding of Steel in Relation to the Occurrence of Pipe Blowholes and Segregates in Ingots," by H. Brearley, *Jour. Iron & Steel Inst.*, 1921.

⁹C. G. Lutts, "Chain Cable by Power Welding"; *Trans., A.S.T.M.*, 1920 II, p. 81.

mer. The scarfs are then brought to a welding heat (about 1,350 to 1,450 deg. C.) in an oil-fired forge, and quickly removed while hot and dripping with slag and welded by drop forging under a fast-working 250-lb. steam hammer, as shown at the right of Fig. 14. Its final shape is given without reheating by dies under a heavy steam hammer in the background, the flash cut off with a chisel, the stud set in place and link closed in by the same hammer.

The use of heavy machinery in this manner permits much greater reduction during forging and a longer scarf than a hand-made chain, as well as less concentrated heat, and consequently a longer welded surface. Undoubtedly a better joint results. However, the tendency is to start and finish at a higher temperature, thus permitting the growth of a relatively coarse columnar grain (Figs. 15 and 16), closely related to that existing in overheated steel, especially in those regions containing an appreciable amount of carbon.¹⁰ Pearlite

heat-treatment is much like that for low-carbon steel: the rate of cooling after annealing is important—furnace cooling results in softness and low strength.

HAMMER WELDING

Mechanical welding, extending the principles of hand-forging to the commercial manufacture of very large pipes and tanks, originated in Germany. Recognizing the advantages of seamless construction in many power accessories, heavy steam drums and receivers have been made in this country for the past six or seven years. The Continental Iron Works, of Brooklyn, have made large tubes for many years, their principal use being for corrugated fireboxes for marine boilers. The American Welding Co., of Carbondale, Pa., and the American Spiral Pipe Works, of Chicago, have also plants for hammer welding; the former specializes in gas containers and bottles, while the latter operates on comparatively light plate. More recently the Blaw-Knox

Fig. 17. Structure of weld after annealing at 950 deg. C. and air-cooling.

then accumulates in angular patches between the elongated grains, the whole structure being definitely unreliable. It presents a minimum of grain interlocking, a maximum extent of crystalline cleavage planes, and is especially weak under shock or alternating stresses. Under tensile stress its most typical manifestation is a low yield point. (It may also be noted that Miller¹¹ finds that several brittle fusion welds had columnar grains.)

In welding chain links, this structure causes brittleness and stiffness. Under test the link is unable to stretch and adjust its shape, consequently it breaks in shear at the quarter points. If the completed chain is heated up to 950 deg. C. (requiring 3 hr. to get there) held for 10 min. at that temperature (slightly above A_c) and air-cooled, it restores equi-axed, normal sized grains shown in Fig. 17 and correct physical properties. The wrought iron from which the links are made at the Boston Navy Yard is quite irregular in carbon content, analyzing 0.05 to 0.08 per cent C, and containing patches two or three times as high. Consequently

Co. and the National Tube Co. have built modern hammer-welding plants in the Pittsburgh district for the manufacture of heavy seamless pots, tanks, pressure vessels and pipes of mild steel plate. Thus the process is gradually coming into use in this country, despite the rather meager amount of current information available about the methods.

It may readily be seen that though the principles involved and precautions necessary in forge welding of small bars, power welding of chain and hammer welding of plate work are the same, the fixtures are different, if for no other reason than adaptability to the shape and bulk of the work. In other words, whereas chain links can be rapidly swung from fire to hammer, a 10 x 20-ft. boiler must be held nearly stationary and the fire, hammer and anvil brought to it.

Briefly, the method is as follows: The various plates, bent or pressed to shape, are assembled with lap joints, and stitched together here and there by a short torch weld on the edge. The assembly is then placed on a carriage, joint up. A pair of gas flames are held one above the seam and the other directly below. When that region has been brought to a proper heat, the upper and lower torches are quickly replaced by an air hammer and anvil respectively, and the hot spot welded and

¹⁰"Heat-Treatment of Wrought-Iron Chain Cable," by W. W. Webster and E. L. Patch, *Trans., Soc. Mech. Engrs.*, 1916, vol. 38, p. 1159.

¹¹"Path of Rupture in Steel Fusion Welds," Bulletin 146, Am. Inst. Min. Engrs., p. 311.

worked down flat. This cycle is repeated until the seam is welded continuously from end to end. When all the seams are finished, the whole article is annealed; all fixtures applied, and if it is a pressure vessel, it is subjected to hydraulic test.

Such operations can best be described by tracing the course of a job through the shop. This will be done in two subsequent articles, descriptive of the plant and practice of the Blaw-Knox Co. and the National Tube Co. respectively. However, it may be noted here that the excellence of well-made seams welded in this manner has been often proved and is now generally accepted. Various names for the process have been used, such as "forge welding," "pressure welding," "fire welding" or "horn welding." The Germans use the term "Wassergas-schweisserei" (water-gas welding). But in all cases their distinguishing characteristic is that they describe a wrought joint, a joint guaranteed by its makers to develop at least 90 per cent of the strength of the plate.

Open-hearth firebox steel is quite suitable for hammer welding. The American Society for Testing Materials has issued tentative specifications¹² covering plates for forge-welded tank cars and similar containers. One of the leading manufacturers of seamless tanks feels that the chemical analysis, especially the silicon content, is very important, and insists on lower limits than the above-mentioned specification. The properties of this plate and a satisfactory weld are as follows:

Carbon.....	0.18 max. (no 25 per cent excess allowed)	
Phosphorus.....	0.035 max.	
Sulphur.....	0.035 max.	
Manganese.....	0.40 to 0.60	
Silicon.....	0.04 max.	
Copper.....	0.04 max.	
Nickel.....	0.05 max.	
Chromium.....	0.05 max.	

	Plate	Weld
Elastic limit.....	32,500	24,000
Ultimate, minimum.....	50,000	
average.....	52,000	48,000
Reduction in area.....	60%	40%
Elongation.....	26% in 8 in.	15%

Since the efficiency of a joint in lap-welded pipe is somewhat lower than that of hammer-welded seams, it is only natural that the weld would be easier to detect in the former. A polished section of lap-welded pipe usually has the weld line visible to the unaided eye, marked by fine specks of included slag. Hammer welds must ordinarily be deeply pickled with strong acid before showing a similar alignment of tiny pits. Fig. 18¹³ shows the appearance after pickling of a hammer-welded plate. The utter elimination of slag inclusions is perhaps impossible, but in a weld having 95 per cent strength or more they must be held to the extreme minimum.

Experience has shown that defective welds can be

FIG. 18. LOW-CARBON
PLATE WELDED
AFTER HEATING

GAS. $\times 1.5$

traced to (a) the welder, (b) the weld itself, (c) thermal disturbance in the stock. Labor-saving equipment in the hammer-welding plant evidently reduces the liability that the work will be slighted by the operator—his own personal equation is almost eliminated. Temperatures of the sheet can readily be controlled by pyrometer, the heating flame is clean and its composition under close control, while an air compressor assumes the labor of heavy sledging. Hence there is little excuse for wrong heat or insufficient work or dirty welds, those most prolific causes of weak joints. Finally, thermal disturbance in the underlying metal is reduced to a minimum by the concentration of the flame, by the ease with which the object is manipulated so that any desired spot can be worked under the hammer, and especially by the annealing given the completed piece. Under these conditions it is not surprising that a joint having much higher efficiency than a riveted joint is regularly produced.

FIELD FOR HAMMER WELDING

A great many common operations in the chemically controlled industries require dependable pressure vessels which are subjected to sudden and rather wide variations in temperature, and yet contain volatile substances which penetrate almost microscopic openings. Riveted stills, for instance, are continually being caulked. Again, annealing pots for use in sheet and tin plate works or wire mills must be subject to wide temperature ranges and yet be absolutely gas tight and free from those cracks which rapidly grow in cast boxes. Cyanide hardening pots are also exposed to severe temperature stresses and corrosive action. Cast vessels now in use are very expensive, brittle and unsafe against heavy pressure. Riveted joints are leaky and often present a concentration of metal where it is least desired. Hammer welding thus seems to have a certain exclusive field. Furthermore, it is of great promise in plain welding work and in manufacturing large-diameter hydraulic lines.

It is also obvious that welded pipe lines, with smooth interior surfaces, will carry a greater amount of fluid for a given pressure head than a line which is roughened by a multitude of rivet heads. This combines with the increased joint efficiency in making a very material saving in weight in pipe lines performing a specified duty on hydroelectric installations, irrigation and aqueduct lines, high-pressure fire lines, and conduits for air, gas and steam.

Hammer welding thus seems to have a certain unique application to the needs of modern industry not now adequately met by any other style of joint.

Commercial Possibilities of the South Sea Islands

Greater interest is constantly being manifested in the commercial possibilities of the South Sea Islands, according to a recent issue of the *World Salesman*. Hardware, including such articles as mugs, iron pots and pans, bedroom ware, and similar goods, is in constant and growing demand in Tonga. In Samoa American exporters have gained the trade formerly conducted by Germany, while in Tonga recent figures show that American firms are taking a good share of the trade, and in Fiji the steadily growing participation of the United States in the copra trade is paving the way for larger importation.

Glimpses of Ohio Ceramic Industries—I

Ohio the Largest Producer of Ceramic Ware — Work of the Bureau of Mines and State University in Furthering Clay-Working Industries by Scientific Research and Training—Stoneware Plants at Akron and Near Roseville

BY CHESTER H. JONES

WHILE the ceramic industries fall under five general divisions—namely, clay products; cements, limes and plasters; glass; enamels for metals, and abrasives—the purpose of this article is to deal chiefly with descriptions of some Ohio plants which are in the first-mentioned class.

The total value of all ceramic products made in the United States in 1918, according to the Bureau of Mines, amounted to about \$447,000,000. Of this sum \$222,000,000, or nearly one-half, represented clay products. Of these clay products 76 per cent were embraced by brick, tile and other structural materials and 24 per cent by the finer grade wares classed as pottery. The four leading states in the percentage of the total valuation of each were: Ohio, 23.8 per cent; Pennsylvania, 18.2 per cent; New Jersey, 9.3 per cent, and Illinois, 5.6 per cent. Ohio produced as much as the states of New Jersey and Illinois combined, or an amount nearly equal to one-fourth of the nation's output.

The annual production of the white pottery classed as "tableware" in the United States was \$31,600,000, with Ohio's annual production at about \$16,500,000, or 52.2 per cent of the output. Summarizing, then, for the state there is produced annually 17.4 per cent of all ceramic products, including clay products; 23.8 per cent of all clay products, including white pottery; and 52.2 per cent of the white pottery, including "tableware."

The state has approximately 550 different clay-working plants with an average production of \$96,000 each annually. While nearly every county has one or more plants, the southeastern half is the more prolific territory for the clay-working industry. Because of the concentration and extent of these fields and the nature of the production processes there are more ceramic problems in Ohio needing solution, more opportunity for application of technical control and research in clay products than in any other state.

BUREAU OF MINES STATION

Ohio clay plants are particularly fortunate in having the Columbus Experiment Station of the U. S. Bureau of Mines located at Ohio State University, Columbus. The work at this station is devoted almost entirely to ceramics and because of its location, it is able to be of peculiar service to the district while developing facts for the industry in general. Research is carried out under the direction of R. T. Stull, and embraces the investigation of ceramic raw materials, their mining and utilization in the manufacture of finished products, the investigation of ceramic manufacturing problems with the object of finding ways of eliminating waste, to reduce the cost of production and to improve the quality of the products. Examples of the nature

of this work are found in reviewing one or two of these investigations.

RESEARCH ON GRAPHITE CRUCIBLES

Prior to 1914 practically all graphite crucibles manufactured in the United States were made from Ceylon graphite bonded with German Klingenberg clay, and the general belief among manufacturers and users was that good crucibles could not be made from American bond clays and graphite. The station undertook the investigation of American bond clays in order to determine their crucible-making properties, and after much work finally found twenty clays which appeared to be promising, eighteen of which were domestic products. Two of the latter were excellent for brass and eleven for steel melting. Over 40 per cent bond clay was used in the blend. The different phases of the work have been published and the crucible makers have been quick to profit by it. In so far as has been determined, no German Klingenberg clay is used in America at the present time and it is gratifying to note that some crucible makers advertise the superior quality of their crucibles as due to the use of the best American bond clay.

DOLOMITE REFRACTORIES RESEARCH

Large quantities of magnesite refractories are used for furnace linings in the metallurgical industry. Before the war substantially all the magnesite used for the manufacture of refractories came from Austria and Greece. When Austria entered the war the exportation of magnesite was cut off and soon afterward the exportation of the Grecian product stopped. The Columbus Station undertook research and patented processes of preparing dolomite for refractory purposes. It is hoped that firebrick can be made from dolomite that will compare with the magnesite firebrick, thus developing a new industry of far-reaching importance. Ohio, with its thousands of acres of dolomite to furnish the raw material for firebrick and its cast-iron and steel industry to utilize them, will profit more than any other state by this work when it is completed.

Investigations which have been running are still under way at this station and may be summarized as follows:

1. Physical properties of the white clays east of the Mississippi River as compared with the imported clays.
2. Tests on clays for the U. S. Geological Survey.
3. Co-operative investigation of Ohio fireclays.
4. Crucible-making properties of domestic bond clays and graphites as compared with the foreign.
5. Properties of dolomite as a refractory for furnace linings.
6. Brick suitable for malleable iron furnace bungs.
7. Load tests of firebrick at furnace temperatures.

8. Luster compositions for pottery decoration.

9. Physical properties of two California clays.

At the end of this article will be found a list of the publications which have been prepared at the Columbus Ceramic Experiment Station up to the present time.

OHIO STATE UNIVERSITY

The course in ceramics at the Ohio State University, which has the main object of developing ceramic engineers for the industry, was arranged to co-operate with the Bureau of Mines station with a view to increasing efficiency in the utilization of mineral resources necessary to the ceramic industry, stimulating and upbuilding this industry in the United States and substituting ceramic products of American manufacture for those now imported. Aside from the excellent work and service done with the bureau station, this school, under the direction of Prof. Edward Orton and Prof. A. S. Watts, produces engineers who are invaluable to the industry and upon whom depends its development in the highest sense.

In visiting the various plants briefly described in the following paragraphs it was pleasing to find that the executives and technical men therein all turn toward the Bureau of Mines station and the university for inspiration and help.

The U. S. Stoneware Co.

Located in Akron, Ohio, the U. S. Stoneware Co. has been known for more than fifty years as a producer of superior quality common stoneware. Twenty-five years ago it developed a chemical stoneware, which has high heat-resisting qualities as well as acid- and alkali-proof features. This last-mentioned line has been so greatly in demand it is now the major portion of the company's business. The raw clays from which both classes of ware are manufactured come mostly from mines owned by the company and located near the plant. They are properly blended during the refining process to get the required body for the final product. The company claims a superiority of ware due chiefly to the excellent and uniform quality of this clay, which is in thin veins so far below the surface that it must be mined through an entry slope, in much the same manner as coal is taken out.

CHEMICAL STONEWARE PROCESS

The raw material is brought from the mines both in automobile trucks and by rail. It is dumped into bins below the grade, whence it is drawn to the wet pans or chasers as the case may be, depending on the type of body desired.

Part of this clay is treated by the wet process and is dumped from the bins to an 8-ft. washer, where water is added during the mixing and grinding operation, the total time consumed per batch being about twenty minutes. From the washer it is transported to a blunger or agitating tank, where it is whipped to a fine creamy consistency in water solution. From the blunging operation this creamy slip is passed through a revolving screen, which removes any large or gritty particles. It passes from the screen to a large cistern, where it is kept in constant agitation until pumped through the plate type filter presses. The cake removed from these presses is the plastic material used in molding certain types of stoneware.

Various bodies and mixtures are required when ware

is to be produced for resistance to corrosive liquids, and for some purposes the raw clay is treated in the chaser mill. The time required for each batch is about two hours. It is ground very fine with a minimum amount of water added until a tough plastic material is made.

SHAPING

The company advocates the use of standard shapes in laying out chemical plants instead of the employment of special shapes to fit individual layouts. Large numbers of standard pieces are produced to fill orders from stock with greater dispatch. Molding of special shapes of stoneware where plaster of paris molds are employed becomes expensive because of the continual necessity for discarding the mold.

Much of the clay is hand-beaten or "batted out" just before shaping on the jollies, as in the manufacture of chinaware, to get a denser body. Special pipe shapes and fittings are also formed in molds. No chemical stoneware pipe is produced on the sewer pipe steam press, since it is essential that all chance of laminating the clay be avoided. The smaller pieces of stoneware are made on the jolly, a form of horizontal potter's wheel with mold of cup shape so as to give the outside contour desired while the inner surfaces are formed by the hand or tool as the whole turns on the vertical axis. Large pieces such as receivers, tanks, pipe and fittings, Cellarius tourills, tower parts and covers are molded in plaster of paris molds, the clay being worked into shape by hand. Large stoneware jars are thrown in a Week's jar machine. Carboy stoppers are pressed from a dry clay.

DRYING, GLAZING AND BURNING

All ware is given careful treatment during drying. The pieces are placed over grated floors beneath which steam pipes are laid. Although the body of the stoneware is acid-proof, additional protection is obtained by completely covering it with a special glazing material before burning. This glaze is made up according to a special secret formula which has been developed after considerable investigation and research. In appearance

FIG. 1. STONEWARE IN KILN, BEFORE BURNING

it resembles the original acid-proof clay. The various glazes used for chemical and common stoneware employ, as the principal apparatus used in the making, a Patterson pebble mill, where the wet grinding is carried out. For common stoneware, white glazes are made chiefly from kaolin and ball clay; the darker colors are obtained with Albany and Michigan slips. The chemical stoneware glaze gives a yellow color to the finished pieces.

FIG. 2. STONEWARE IN KILN, AFTER BURNING

Another product of this factory is the pot used in the manufacture of white lead by the old Dutch process. The lower portions of these pots where the acetic acid is held are covered with the acid-proof glaze.

The burning equipment consists of seven down-draft periodic kilns of 32 and 34 ft. diameter, which burn coal from the Ohio mines, owned by the company. Figs. 1 and 2 show pieces of common stoneware stacked in kilns before and after burning respectively. In Fig. 1 the bats separating the jars to prevent the glazed pieces from melting together are seen. These bats are simply small burned pieces of clay. The dark glaze on top and the lighter glaze on the bottom of inverted jars are seen in the left of this picture. Fig. 2, giving view of the partly emptied, finished kiln, shows how pieces of equal size are built in tiers up from the floor for equal distribution of draft with the odd shapes piled on the top to get the best heat zone without interfering with the draft. Cones are used in heat control.

Some of the common stoneware pieces are made on the steam sewer pipe press, others on the jar machine and the jugs and odd round pieces are thrown on jollies. A wide variety of chemical and common stoneware products are placed on both markets. Three switches lead trackage into the plant, giving connections for shipment on four different railroads.

Ramsbottom Bros.' Pottery Co.

The Ramsbottom Bros.' Pottery Co., located near Roseville, in the southeastern Ohio district, is one of the largest concerns engaged in the manufacture of common stoneware products. It was organized about ten years ago, the factory being constructed in the district where the necessary raw product was easily available. The native clay is mined in the vicinity of Rose-

FIG. 3. TRAM BUCKET HANDLING CLAY FROM PUG MILL

ville and Ironspot, being obtained by drifting into the hillside after the manner in which coal is mined. The overburden is so great that it is not possible to strip it off to get at the required seams. Some of these clays are said to be adapted for use in the manufacture of soft gardenware and chemical stoneware, although this company does not produce the latter class of product at the present time.

PROCESS OF REFINING

The clay is delivered on a platform at the plant, coming from the mines in automobile trucks. Three different grades of clay are blended by shoveling from the three piles into a three-way chain conveyor, which feeds each one into a common screw conveyor, where they are automatically mixed while being transferred to the battery of three blungers.

In the blunger the mixture is fed with water and is all whipped up by revolving paddles to a fine creamy consistency and subsequently pumped at 100 lb. pressure to the filter presses. The water from these filter presses is returned to a cistern, where it is kept in

FIG. 4. JIGGERS

constant agitation and again returned to the blungers for further mixture. From the filter presses cakes which have a consistency of putty are fed into the large pug mills.

While these mills are working out the air and extruding the finished powdered material at the far end, the clay is tempered with a clay slip in place of the clear water commonly used. This clay slip is the type of material that is taken from the blungers to the filter presses. The consumption of raw clay at this plant is about 80 tons per day.

Common practice in most pottery plants is to transport the tempered clay from the pug mill to the jiggers and molding rooms by wheelbarrow. It is in this feature, as well as in other mechanical equipment, that the company has improved over the practice at other plants. Fig. 3 shows an operator at the delivery table of the pug mill in the act of starting off a bucket of

clay to the modeling room. The entire output of the plant is handled by one man, who throws batches of clay either into the tram buckets or onto a shelf elevator, the latter of which delivers clay to the jar machines on the upper floors.

This aerial tram is fashioned after the manner of a mining type or hay-transporting type of equipment and travels along a cable directly over the row of workmen's benches. When the workman desires an additional supply of clay for his molding or jiggering operations he simply throws in a lever which stops the bucket and automatically dumps it. It is then returned to the pug mill for another load. The clay which is sent up on the shelf elevators to the jar-throwing machine is automatically cut at the pug mill to furnish just the

FIG. 5. FILLING MOLD ON JIGGER

right amount of clay for each jar. These jar machines are essentially steel-cased jiggers operated by an interior rolling device for running the clay up the side of the jigger.

Fig. 4 shows a row of jiggers for casting jugs, butter jars, etc. The clay tram is seen just dumping at one of the benches. Fig. 5 shows an operator placing the clay in the interior of the plaster of paris mold on the potter's wheel before he brings down the jigger lever to the left for forming the true interior of the piece. Common stoneware jugs are made in two pieces, the top being separate from the bottom and the two parts of clay later joined and worked together by the hand. The jug handle is later placed on by hand, the clay being wet down to cause it to form one piece with the side of the jug.

The steel jiggers for producing the big jars are lined with paper to prevent the paper from sticking to the metal. These particular Week's machines have revolutionized the industry so that one man can do the same amount of work in twenty-four hours that was previously done by five. Different steel molds are used for producing sizes from 5 to 50 gal. capacity.

STEAM AND POWER

Power for operating the various machinery around the plant is furnished by a 60-hp. induction motor, which drives the shafting for one section of the plant, and the remainder is driven by a 125-hp. steam engine. The total boiler installation is 300 hp. The steam from

these boilers, after passing through the engine, is conducted in the steam piping to the rooms for drying the ware. The coal supply for the boilers is mined from the same locations as the clay properties.

DRYING

The drying rooms are located adjacent to the jiggers and molding rooms and consist, on the first floor, of a series of steam pipes overlaid with a wooden grating. Above this grating is located the shelves upon which the ware is placed. The heat from the drying room on the first floor is carried through openings to the second floor, where the larger pieces from the jar machines are placed. This upper compartment consists of a large open room with a low roof. It is in this room that the plaster of paris molds are made for use on the jiggers. Each mold gives about one year of service before it has to be replaced.

GLAZING

Two general types of glazes are used for the stoneware, one the dark color and the other the white glazes. Feldspar, zinc, whiting and ball clays are used in the manufacture of these plain glazes, and Albany and Michigan clays are used for colored glazes. The dried ware is glazed on the outside by dipping into a vat and on the inside by inverting a jug over a spigot, for instance, and pushing down a lever which sprays the inside of the piece, entirely covering it with glaze. After this is done the bottoms of the pieces are washed off to prevent them from sticking in the kiln.

BURNING

The kiln room equipment consists of thirteen down-draft periodic kilns 30 ft. in diameter. A battery of four kilns is exhausted through a common stack. Natural gas is used for fuel, coming from the Ohio Fuel Supply Co., which taps the West Virginia field. Fig. 6 shows kiln under fire with large stack on the left.

The ware is loaded into the kiln in all sizes, the larger pieces being separated by bats or small pieces of burned

FIG. 6. DOWN-DRAFT PERIODIC KILN UNDER FIRE

clay, to prevent the glazes from sticking during the burning operation. No saggers are employed. The time required for burning is a three-day cycle. Only one burning is required for both body and glaze, the temperature reached varying from cone 8 to cone 9.

The scrap, or refuse, from molten stoneware in this plant is so completely vitrified as to make an excellent material for grog, and is sold by the carload to various

other clay plants. All the broken stoneware is dumped into a bin below the level of the kiln room floor, whence it is carried up by a specially designed Jeffrey chain elevator for dumping into wagon and automobile trucks and conveyances to the dumping platform on the railroad.

PRODUCTS

The chief output of this plant is stoneware jugs, flower pots, jars, cuspidors, frost-proof gardenware, butter jars, home brew jars and other domestic stoneware. It is extremely interesting, in looking over the products in the storage room, to note that an entirely different type of stone jar is manufactured for use in Pennsylvania as compared with those used in the southern section of the United States. The Pennsylvania jar is a rather tall rounding shape, with a comparatively small bottom, so that it may be placed in the running water at the dairy house, while the jar used in the South is provided with a groove below the lip so that a cloth cover may be tied over and secured by a string running around the groove. The entire output is marketed through the American Clay Products Association.

Not unlike many other clay-working plants, the morale of this organization is maintained by direct contact between the workmen and one of the partners, who acts as superintendent of the plant. There was considerable difficulty in this section recently in getting an adequate supply of labor. The workmen were lured away by the high prices paid in the coal mines in the same territory. Since the business depression, however, the workmen are gradually returning to the clay-working industry. Another feature worthy of note is the fact that about 45c. per thousand feet is paid for natural gas used in burning the ware. This charge is increasing every year, and it is only a question of a short time when the company will be forced to convert the kilns so that coal may be used as fuel.

It is predicted that it is only a question of time when the wet process of producing the tempered clay for pottery work will be replaced by the dry process, where the clays are ground to pass a 100-mesh screen and stored away for aging for a period of from thirty days to three months. This aging destroys the effect of lining and breaks up the otherwise hard lumps in the clay, so that eventually more plastic material is produced.

Treated Wood Gives Increased Yield of Methanol*

An increase of 50 per cent in the yield of methanol may be obtained by means of an inexpensive treatment consisting of the addition of a small percentage of sodium carbonate to the wood before distillation. Experiments show that this increased yield may be obtained without diminishing the yield of acetic acid. Contact of the carbonate with all of the wood is necessary to obtain the full benefit of the treatment; hence the method is likely to prove the most valuable in connection with the distillation of sawdust or small blocks, because of the difficulty of getting thorough impregnation with larger pieces. Saturation with a solution of the carbonate is a sufficient treatment for the sawdust, but a pressure treatment is necessary to impregnate the wood blocks.

Below are some of the actual results obtained at the laboratory.

SAWDUST UNTREATED AND TREATED WITH SODIUM CARBONATE AND BRIQUETTED

Species	Catalyzer	Yield in Per Cent of Original Weight		Remarks
		Alcohol	Acetic Acid	
Maple.....	None	1.61	5.22	Average of 4 runs
Maple.....	1.5%	2.39	5.26	Average of 3 runs
White oak.....	None	1.17	4.91	Average of 2 runs
White oak.....	0.5%	2.58	5.09	

BLOCKS OF WOOD UNTREATED AND TREATED WITH SODIUM CARBONATE

Species	Catalyzer	Alcohol	Acetic Acid	Remarks
Maple.....	None	1.67	7.65	
Maple.....	1.12%	2.16	6.74	Pressure treatment
Oak.....	None	1.20	5.56	
Oak.....	1.03%	1.79	5.58	Pressure treatment

Other amounts and other chemicals were tried, but the results given are the most promising of any.

Improved Method of Electrolytic Etching for Microstructure

BY W. VELGUTH

ELECTROLYTIC etchings are usually very flat, of one uniform color as shown in Fig. 1, and while this method of etching brings out a good structure, better results can be had by cleaning the specimen to be etched. The true orientation of the grain structure can be brought out more clearly by first cleaning the specimen electrolytically in a caustic solution or in a solution of sodium thiosulphate, and then etching electrolytically in acid.

In determining the microstructure of the nickel alloys used for negative terminal of base metal thermocouples both these electrolytes were used to good advantage, as can be seen from the accompanying micrographs. Using a 10 per cent solution of sodium thiosulphate as the electrolyte, the polished specimen is made the cathode and a carbon rod the anode. On a 10-volt, direct-current circuit, with a current density of 1.55 amp. per sq.in., the specimen is cleaned in five to ten seconds. With a drop of the thiosulphate solution adhering to the polished surface, the sample is transferred to a 10 per cent solution of hydrochloric acid. The sample is now made anode and a carbon rod is the cathode. With a current density of 0.62 amp. per sq.in., most of the microstructure shown in Fig. 2 can be developed in eight to ten seconds. Contact was made with the specimen before it was lowered into the acid. If the sample was washed free of thiosulphate before it was transferred to the acid, results were uncertain.

When the etched specimen is removed from the acid, the surface will be a dull gray or blue. Wash it gently in a stream of water; shake off all surplus water, and dry in a blast of warm air. The surface now takes on various shades of color, and is bright and clear. Some of the etchings were shades of blue, purple, green or red, while again in some instances each grain area had a different color. This coloring in no way interferes with the details of the microstructure.

Cleaning the specimens electrolytically in a 10 per cent caustic solution also gave good results when followed by electrolytic acid etching (Fig. 3). but the colors produced were shades of yellow only.

Resistance Type Electric Furnace for Sheet Heating

In the manufacture of automobile body and fender stampings it is of the highest importance that the heating operations be conducted with as little scaling as possible, for any pitting due to this action requires considerable additional labor in getting the defects sand-blasted to sufficient extent to get a good finish on the part.

The Mullins Body Corporation, Salem, Ohio, with this in mind recently installed in its new plant a Baily electric furnace specially designed for this work. Since a large part of pressing or drawing to shape done by this concern is performed cold and only one or two hot runs are required for perhaps six or seven cold operations on the press, it was desirable to build a furnace of

ELECTRIC FURNACE FOR SHEET HEATING

the portable type which could be handled by a crane and taken from place to place so that there would be no idle furnaces while the material was receiving its cold runs. This necessitated a furnace with four eye-bar connections at the top, one at each corner, for hooking on the crane chains; and also that the transformer and control equipment be located on the top of the furnace, as is shown in the photograph.

The furnace is rated at 100 kw. in electrical capacity, and has a hearth 3 ft. 4 in. wide x 6 ft. 5 in. long with

Fig. 1. Electrolytic etching in acid solution.

Fig. 2. Cleaned in sodium thiosulphate before acid etch.

Fig. 3. Cleaned in caustic solution and etched in acid with current.

FIGS. 1 TO 3. MICROSTRUCTURE OF NEGATIVE THERMOCOUPLE WIRE AS DEVELOPED BY DIFFERENT ELECTROLYTIC METHODS

a door opening 3 ft. 4 in. wide x 2 ft. 2 in. high. It has a capacity for heating 750 lb. of material to 1,800 deg. F. per hour. In plants where a crane is not available for moving the furnace the equipment is designed for mounting on a car which may be moved at the will of the operator on a track running parallel to the battery of presses.

One of the notable features of this equipment is the remarkable uniformity of temperature obtained on the sheets. Scaling is also reduced to an almost negligible item.

Synopsis of Recent Chemical & Metallurgical Literature

Nitrogen Products.—A statistical supplement to the final report of the Nitrogen Products Committee of the British Ministry of Munitions has recently been compiled by Dr. J. A. Harker, the former director of the Nitrogen Research Laboratory. In addition to bringing all of the statistical information up to date, the supplement presents a concise and interesting review of recent developments in the world's nitrogen industry. The former report had been prepared during the war period and did not cover the latter half of 1919 nor any of 1920.

It is of interest to compare the situation as regards the sources of the world's nitrogen supply before the war and at the present date. In 1912 the output of Chilean nitrate was 2,586,975 metric tons, equivalent to 411,329 tons of nitrogen. This was 57.5 per cent of the total world's production. The byproduct industry produced 1,229,773 tons sulphate of ammonia (containing 24.5 per cent ammonia), or 272,007 tons of nitrogen (38 per cent of total). The fixed nitrogen industry's output was as follows: (a) Cyanamide (assumed 18 per cent N) 126,538 tons, nitrogen 22,435 metric tons (3.1 per cent of total); (b) nitrate of lime and arc process (assumed 13 per cent N) 75,000 tons, nitrogen 9,907 metric tons (1.4 per cent of total); (c) synthetic ammonia, nil; total of fixation industry 201,538 tons, nitrogen 32,342 metric tons (4.5 per cent of total). Grand total, 4,018,286 tons of product, nitrogen 715,678 metric tons.

Comparing with the above the productive capacity existent in the world in 1920, that of the Chilean nitrate industry is given as 2,966,061 tons, the productive capacity of nitrogen being 471,000 metric tons, or 30.2 per cent of the world's total. The byproduct industry, 2,015,440 tons, nitrogen 413,000 metric tons (26.6 per cent of total). The fixation industry: (a) Cyanamide 1,777,000 tons, nitrogen 325,000 metric tons (20.9 per cent of total); (b) nitrate of lime and arc process 290,400 tons, nitrogen 38,300 metric tons (2.5 per cent of total); (c) synthetic ammonia 1,503,000 tons, nitrogen 308,000 metric tons (19.8 per cent); total of fixation industry 3,570,400 tons, nitrogen 671,300 metric tons. Grand total, 8,551,900 tons of product, nitrogen 1,555,300 tons.

Allowance must be made for the fact that the 1912 figures are for actual production, while those of the later year are for productive capacity. It is particularly significant, however, that during this period the world's nitrogen resources have doubled; and that while the percentage of the total contributed by Chilean nitrate *decreased* to one-half, the output of the fixation industry has *increased* almost tenfold, or from 4½ per cent of the whole in 1912 to 43 per cent in 1920. The fixation industry is now the largest single contributor to the nitrogen requirements of the world. It is interesting to note, too, that in spite of the much-talked-of developments in synthetic-ammonia manufacture, the cyanamide installations during the war period have made this process the largest of any of the fixation methods.

Synthetic Acetic Acid.—The manufacture of synthetic acetic acid from calcium carbide is described at length by Maurice Deschiens in a series of three articles published in the March, April and May, 1921, issues of *Chimie et Industrie*. A flow sheet shows the importance of acetylene as a raw product for the manufacture of some of the long series of commercial organic chemicals. The manufacture of calcium carbide, generation of acetylene, hydration of the acetylene to acetaldehyde and the oxidation of acetaldehyde to acetic acid are described.

Manufacture of Calcium Carbide.—After giving the average analysis of the raw materials (limestone, anthracite, coke) used in Europe, United States and Canada, he describes the operations of the Hafslund furnace (Norway) and of different other furnaces of the single-, two- and three-phase types.

Generation of Acetylene.—He describes in detail the Grivel process used in France and then outlines a series of the processes used in Switzerland, United States, Canada and Germany.

Hydration of Acetylene to Acetaldehyde.—After outlining the preparation of mercuric oxide which is used as catalyzer and describing in detail a process for the preparation of acetaldehyde and rectification to 99.8 per cent purity, he passes in review a long series of other processes used, giving the sources where they are described somewhat more in detail.

Oxidation of the Acetaldehyde.—For the oxidation of the acetaldehyde he follows the same rule as for the hydration of acetylene to acetaldehyde—namely, by first describing in detail a typical process and then outlining a long series of other processes, here also giving the sources where they are described more in detail.

He concludes by giving a brief outline of the potentialities of the synthetic acetic acid industry and by tabulating a long series of articles and patents (German, English, American and French) on synthetic acetic acid.

Wheel Burnt Rails.—C. P. Sandberg read a paper before one of the engineering conferences held by the British Institution of Civil Engineers, June, 1921, entitled "Damage to Tires and Rails by Brakes or Slipping Wheels," in which he described the same phenomena discussed by J. E. Howard¹ in a report to the Interstate Commerce Commission. Sandberg finds a hardened surface, crossed by a multitude of transverse cracks, on tires, brake shoes, tramway and railroad rails, all caused by intense local heating by friction. He agrees with Howard that they are potential causes of failure to railroad rails, which, being supported at intervals, readily allow growth of the damage inward. Tramway rails and wheel tires, however, being solidly supported throughout, are not liable to "detail fracture" from such causes. The author describes the formation of the surface cracks thus: "Sliding of one surface over the other proceeds to a point at which both are hot, soft and plastic, and tend to seize together momentarily at numerous points. While so united the surface layers are dragged bodily forward, forming an overlap in advance of each area of adhesion and a tear behind it. Alternating seize and slip probably occurs many times per second during the application of brakes, producing a series of surface tears or cracks in both brake and wheel, at right angles to the direction of motion."

Latest About the Basset Process.—On the subject of the Basset process the *Iron Trades Review* of Aug. 19, 1921, states that according to the recent annual report of the Ougrée Marihay Co., which is interested in the Société Française des Aciéries Basset, the process has not yet reached a phase of development which would enable one to arrive at an estimate of the costs of production or to form an opinion as to the value of the process. At the recent general meeting of the Ougrée-Marihay Co. a shareholder asked the chairman as to the exact meaning of this passage, and whether any new trials have been made since the date of the annual report. He was told that the process was still in its experimental stage, and that since the drafting of the annual report no new experiments have been carried out.

American Electrochemical Society to Hold Meeting at Lake Placid

The fortieth general meeting, marking the end of the second decade since the organization of the American Electrochemical Society, will take place at the Lake Placid Club, in the Adirondacks, Sept. 29, 30 and Oct. 1.

The technical program will be featured by two symposia, on non-ferrous metallurgy and electrodeposition. The program of the meeting is shown below:

WEDNESDAY, SEPT. 28

6 p.m. Registration at Lakeside Clubhouse.

THURSDAY, SEPT. 29

9 a.m. Presentation and discussion of papers.

Charles Vickers: Experience With Alkaline and Alkaline Earth Metals in Connection With Non-Ferrous Alloys.

W. A. Cowan, L. D. Simpkins and G. O. Hiers: The Electrolytically Produced Calcium-Barium-Lead Alloys Comprising Frary Metal.

Colin G. Fink and Charles H. Eldridge: The Electrolytic Corrosion of Lead-Thallium Alloys.

J. Newton Friend: A New Theory of the Corrosion of Iron.

Haakon Styri: Rust Prevention by Slushing.

C. J. Rodman: Transformer Oil Sludge.

Raymond Freas: The Electrolysis of Organic Compounds.

Alexander Lowy and E. H. Haux: Electrolytic Oxidation of the Leuco-Base of Malachite Green.

N. Kameyama: The Electrolytic Dissociation of Cyanamide and Some of Its Salts in Aqueous Solutions.

P. C. Alsgaard: Electrolytic Production of Sodium Perborate.

H. M. Goodwin and C. E. Walker: Electrolytic Production of Perchlorate.

B. G. Worth: Graphic Control of Electrolytic Processes.

2 p.m. Sports and recreations. Golf match under the direction of Mr. Dorr, chairman of golf committee.

A boat ride has been planned for this afternoon for the benefit of those not participating in golf. There will also be other entertainment under the direction of Mr. Corse, chairman of committee on arrangements. Additional information available at the registrar's desk.

6:30 p.m. Board of directors' meeting, at dinner, for the transaction of usual business.

8 p.m. Meeting in the music room of the Forest Clubhouse.

Lecture by Prof. Harlow Shapley, of the Harvard University Observatory, on "Chemistry and the Stars."

FRIDAY, SEPT. 30

9 a.m. Reading and discussion of papers.

Symposium on Non-Ferrous Metallurgy

H. M. St. John: The Influence of the Electric Furnace on the Metallurgy of Non-Ferrous Metals.

E. A. Smith: Modern Developments in the British Brass Industry.

T. F. Baily: Resistance Type of Electric Furnace in the Melting of Brass and Other Non-Ferrous Metals.

N. K. B. Patch: Comparison of Electric Furnace Practice With That of Fuel-Fired Furnace Practice.

H. A. DeFries: Electric Silver Melting.

F. C. Thompson: Electric Furnace Melting of Nickel-Silver.

H. A. Winne: Recent Developments in Electric Furnaces of the Muffled Arc Type.

J. G. Thompson: Electric-Furnace Purification of Zirkite.

M. L. Hartmann and W. A. Koehler: Physical Characteristics of Specialized Refractories. Part IV.—Cross Breaking Strength at 20 Deg. and 1,350 Deg. C.

2 p.m. Sports and recreations. Continuation of golf match of previous afternoon.

Mountain hiking and other sports, under direction of Mr. Hinckley, chairman of other outdoor sports committee.

Indoor sports will be taken care of by Mr. Crosby, chairman of that committee.

8 p.m. Lecture by Colonel T. S. Woolsey, Jr., on "Practice of Forestry on National Forests"; to be held in the music room of the Forest Clubhouse.

SATURDAY, OCT. 1

9 a.m. Reading and discussion of papers.

Symposium on Electrodeposition

F. A. Lidbury and F. A. Stamps: An Electric Steam-Generator for Low Voltage.

W. E. Hughes: Researches on the Electrodeposition of Iron.

T. R. Briggs: Electrolytic Solution and Deposition of Copper.

W. R. Ingalls: Electrometallurgy of Zinc.

C. J. Wernlund: Deposition of Zinc From the Zinc Cyanide Solution.

William Blum and H. E. Haring: The Electrodeposition of Lead-Tin Alloys.

William Blum: The Structure and Properties of Alternately Electrodeposited Metals.

2 p.m. Golf finals for the society championship, those having qualified in the matches of the two previous days will participate.

Motor bus ride to the Club Farms.

Claim Large Saving for New Phosphoric Acid Process

The Department of Agriculture is sending to all newspapers in the country the following statement with regard to its work on phosphoric acid recovery:

The United States owns the richest and most extensive phosphate fields in the world. Heretofore heavy annual wastes of valuable phosphatic material have occurred during the mining and manufacturing processes. A new method of controlling these losses devised by the United States Department of Agriculture consists in mixing the "run-of-mine" phosphate with sand and coke and smelting the mass in an electric or fuel-fed furnace. In this process the phosphoric acid is driven off as a fume and may be readily collected in concentrated form. Millions of tons of phosphates previously wasted will be saved potentially as a result of the perfection of this new reclamation system.

Society of Textile Chemists Proposed

The organization of a society of textile chemists was considered at a meeting held in the Chemists' Club Sept. 13. A number of representatives of this branch of the chemical industry attended and Prof. L. A. Olney of the Lowell Textile School was elected chairman. From the expressions of opinion there seemed to be little doubt that an organization of this character was a very feasible proposition. Accordingly a representative committee was appointed to study the possibilities in this direction.

List of Research Chemicals in Preparation

In our issue of July 6, p. 35, attention was called to a forthcoming publication of the National Research Council in which research chemicals and others not commonly available will be listed. Dr. C. J. West now requests that all those desiring a copy of this publication notify him at the National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Gypsum Industries' Association Cited for Unfair Competition

The Gypsum Industries' Association, Chicago, Ill., its officers and members have been cited in complaint of unfair competition by the Federal Trade Commission. Thirty days are allowed to file answers to the complaints, which are issued after preliminary inquiry by the commission upon petition filed with it. After answer the cases come on for formal trial on the merits, full opportunity being afforded the companies to refute the allegations of the complaints, to present their witnesses, introduce evidence, etc. Those cited are:

(1) Gypsum Industries' Association, Chicago, Ill., a voluntary unincorporated association, composed of persons, partnerships, and corporations engaged in many of the states in manufacturing and selling gypsum products.

(2) The executive officers and members of standing committees: Ray C. Haynes, president and member of the executive committee, which committee is ex officio the board of directors of said association; James Leenhouts, vice-president and member of the executive and trade relations committee; R. G. Bear, treasurer and member of the executive and trade relations committee; H. H. McDonald, secretary; M. A. Reeb, member of the executive and trade relations committee; A. R. Black, L. E. Armstrong, A. A. Wolf, J. C. Seguire and W. E. Shearer, members of the executive committee; H. W. Blackson, Warren Hanley, E. G. West, H. C. Hamilton and F. G. Ebsary, members of the trade relations committee.

(3) Members of the Gypsum Industries' Association as follows: Acme Cement Plaster Co., St. Louis, Mo.; American Cement Plaster Co., Chicago, Ill.; American Gypsum Co., Fort Clinton, Ohio; Cardiff Gypsum Plaster Co., Fort Dodge, Iowa; Centerville Gypsum Co., Centerville, Iowa; Colorado Portland Cement Co., Denver, Col.; Connecticut Adamant Plaster Co., New Haven, Conn.; Dakota Plaster Co., Rapid City, S. D.; Ebsary Gypsum Co., Rochester, N. Y.; Empire Gypsum Co., Rochester, N. Y.; Grand Rapids Plaster Co., Grand Rapids, Mich.; Higginson Manufacturing Co., Newburgh, N. Y.; Kelley Plaster Co., Sandusky, Ohio; J. B. King & Co., New York; Alabastine Co., Grand Rapids, Mich.; Nephi Plaster & Manufacturing Co., Salt Lake City, Utah; Niagara Gypsum Co., Buffalo, N. Y.; Overland Cement Plaster Co., Laramie, Wyo.; Pacific Coast Gypsum Co., Tacoma, Wash.; Plymouth Gypsum Co., Fort Dodge, Iowa; Rock Plaster Manufacturing Co., New York; Southern Gypsum Co., Inc., North Holston, Va.; United States Gypsum Co., Chicago, Ill.; Wasem Plaster Co., Fort Dodge, Iowa.

The basis of the complaint, briefly stated, is the alleged concerted activities of the association members to eliminate mail order competition by restricting sales to dealers maintaining retail establishments, and by a division of territory among members so as to limit each member's sales to the territory reached by delivery trucks of retailers to whom he sells.

Want Alcohol Tax to Stay

The removal of the tax on alcohol would flood the country with fly-by-night concerns making carloads of alcoholic medicinals to sell for beverage purposes, it is contended by the American Drug Manufacturers' Association. The pharmaceutical manufacturers are taking active steps to block the campaign now being launched looking to the removal of the tax on alcohol. They declare that thousands of irresponsible men are being kept out of the manufacture of alcoholic medicinals because of the existence of this tax. A statement issued from the Washington headquarters of the American Drug Manufacturers' Association reads in part as follows:

It is supposed that the removal of the tax would result in a lowering of the cost of medicines, but when you think of the comparatively small amount of a given medicine that goes into a prescription you will realize that the ultimate consumer would not appreciably benefit.

On the other hand, the removal of the tax would simply add to the present depression. The pharmaceutical manufacturer has paid the equivalent of the tax not only on the alcohol now in his warehouse but likewise on the alcohol in the preparations in process

of manufacture, in the finished stocks on his shelves and in his unsold product in the hands of the wholesale druggist and corner drug store. The moment the tax is removed the market value of these products, as well as alcohol, will shrink, and since the wholesaler and retailer would look to the manufacturer for credit on the shrinkage of the stocks in their hands, the manufacturer would be called upon to bear this enormous loss alone, a situation that would probably drive some of them to the wall.

It should be borne in mind, too, that the Government would be deprived of revenue at a time when it is called upon to make other important reductions.

From the Government's standpoint there is likewise the objection that the removal of the tax might prejudice the validity of several features of the Volstead act which do not rest upon the Eighteenth Amendment. The Eighteenth Amendment deals only with the use of intoxicating liquors for beverage purposes and the constitutionality of provisions of the Volstead act regulating the manufacture and sale of liquor for other purposes rests upon the power given Congress in the Constitution to raise revenue.

Tenth Annual Congress of the National Safety Council

The tenth annual congress of the National Safety Council will be held in the State House, Boston, Mass., Sept. 26 to 30, 1921. The following is the summarized program:

MONDAY, SEPT. 26

Forenoon: Annual meeting of members, address by Gov. Channing H. Cox, president's address, reports of officers and committees, election of directors.

Afternoon: General session on public safety and education. First aid demonstrations and motion pictures of first aid contests will be shown.

The reception and dance will be given in the evening at the Copley-Plaza Hotel.

TUESDAY, SEPT. 27

General round table and meetings of the following sections: Automotive, Chemical, Construction, Education, Electric Railway, Engineering, Metals, Mining, Packers and Tanners, Paper and Pulp, Public Utilities, Rubber, Steam Railroad, Textile and Woodworking.

There will also be a meeting of the A B C section and of the local council officers. A series of motion pictures on safety will be shown late in the afternoon.

WEDNESDAY, SEPT. 28

Meetings of the following sections: Automotive, Chemical, Construction, Electric Railway, Metals, Mining, Packers and Tanners, Paper and Pulp, Public Safety, Public Utilities, Rubber, Steam Railroad, Textile, Women in Industry and Woodworking.

There will also be a general session under the auspices of the Engineering Section, on engineering and safety, and the second session of the local council officers.

THURSDAY, SEPT. 29

Meetings of the following sections: Health Service, Mining, Public Safety, Steam Railroad.

There will also be a joint meeting of manufacturing sections and a general session on health and sanitation.

In the evening a shore dinner will be given to the delegates.

FRIDAY, SEPT. 30

Meeting of the following sections: Automotive, Health Service, Mining, Packers and Tanners, Public Safety, Rubber, Steam Railroad and Woodworking.

There will also be a women's mass meeting on the subject of safety of the child and a New England conference on motor traffic problems.

Domestic Potash Industry Marking Time

With the exception of two cement mills and two alcohol plants, no enterprise in the United States is producing potash at this time. The domestic industry is marking time awaiting the final action of Congress on the diminishing temporary tariff described in the tariff bill which has passed the House of Representatives. The plants that are idle represent an investment of more than \$30,000,000.

Coking Studies at Ohio State University

The department of metallurgy of the Ohio State University, under the auspices of and with the funds provided by the Engineering Experiment Station of the university, has installed a full scale 1-ton vertical coal retort, a complete byproduct recovery system equipped with gas meters, pyrometers and recording calorimeters. With this equipment the entire coal resources of Ohio are being surveyed with the view of obtaining accurate information concerning the possibilities of utilization of Ohio coals for gas making, byproduct recovery and coke production. Five-ton samples of each coal to be tested are obtained, duplicate 1-ton samples of this are carbonized under ordinary vertical retort conditions, the tar, ammonia and light oil recovered and analyzed, and the coke made is obtained and its quality determined by chemical analyses and physical tests. The gas made is measured in a recording and integrating Bailey gas meter and its heat value recorded in a continuous recording Smith gas calorimeter. Also a sufficient amount of each coal is crushed, sized, the coarser sizes jigged and the finer sizes tabled on a Wilfley table. The clean coal is then dried and retorted. In this way it is expected that the most complete information possible will be obtained on all of the Ohio coals. Tests will also be made on mixtures of Ohio coals with coals from other states. It is hoped to get all this information so that the cities of the state can make the most intelligent selection of coals for the production of artificial gas to supplement the waning natural gas supply.

Interest in Tariff Unprecedented

Greater interest is being manifested in the Fordney tariff bill than in any other tariff measure ever presented to Congress. An indication of this is the unprecedentedly large number of briefs which have been filed with the Committee on Finance of the Senate. A large force is required to digest and classify the vast amount of material being sent to the committee.

The unusual amount of interest in this tariff bill is accounted for primarily by the fact that American industry has expanded and is much more extensive than it was in 1909, when the Payne-Aldrich bill was under consideration, or in 1913, when the Underwood bill was passing through its various legislative stages. There are additional reasons, however, for the interest that has been aroused by the Fordney bill. The demoralized commercial situation of Europe has given rise to many uncertainties which have stimulated interest in tariff matters. The whole subject of foreign trade has been receiving unusual attention. Interest has been intensified by the consideration of new policies, such as American valuation and the dye embargo. Considering that valuations are to be on an American basis, many of the rates in the Fordney bill are regarded as being very high. This has resulted in the most determined opposition on the part of the interests which would be affected.

Consumers of kaolin have submitted a brief which attempts to establish that the present duty of \$1.25 per ton on English china clay should not be increased. If this duty is advanced to \$2.50, as prescribed in the Fordney bill, it will have the most adverse effect on the paper, pottery and other industries, it is declared.

A very determined effort is being made on the one hand to make graphite dutiable at rates much higher than the rate approved by the House, which is 10 per cent ad valorem. The steel industry and other consumers of graphite, on the other hand, want it to remain on the free list. The domestic producers of graphite propose that ore under 50 per cent graphite content pay duty at the rate of 1c. per lb.; ore over 50 per cent graphite content, 2c. per lb.; lump and chip, 3c. per lb.; flake, graphite content, 6c. per lb.; manufactured graphite products, graphite content, 5c. per lb. and 20 per cent ad valorem.

One of the most carefully prepared briefs which has been submitted to the Finance Committee is that of Roy N. Bishop, for the Western Magnesite Association and for the Northwest Magnesite Co. It is contended that a duty of 1c. per lb. on the ore, 1c. per lb. on calcined magnesite and 1c. per lb. on magnesite brick are necessary to protect the

industry. In the Fordney bill, calcined, dead-burned and grain magnesite are given a duty of 1c. per lb., while crude or ground magnesite is given a rate of 1c. per lb. Even with the duties requested, the American producers contend that the Austrian mines will furnish fully 50 per cent of American requirements.

On antimony, the Fordney bill prescribes a duty of 1c. per lb. on regulus, or the metal. The domestic producers of antimony ask 10c. per lb. upon antimony salts, 10c. per lb. on regulus, metal or matte and 8c. per lb. on the antimony content of ores.

On arsenic, the Fordney bill provides 25 per cent ad valorem on arsenic acid, arsenious acid or white arsenic. The industry asks for a duty of 5c. per lb. on white arsenic.

On barytes, the Fordney bill carries a duty of \$4 per ton on the crude ore, \$7.50 a ton on ground or manufactured barytes and 1c. per lb. on precipitated barium sulphate. The domestic industry asks 1c. per lb. on crude barytes, 1c. per lb. on ground barytes, 1c. per lb. on barium sulphide, 2c. per lb. on barium carbonate, 2c. per lb. on barium dioxide, 2c. per lb. on barium sulphate, 2c. per lb. on barium chloride, 2c. per lb. on barium lithopone, 5c. per lb. on barium nitrate, 8c. per lb. on barium peroxide and 25 per cent ad valorem on all other barium compounds.

Bismuth is on the free list in the Fordney bill. The domestic industry is requesting a duty of 25c. per lb. The same is true of cadmium.

Feldspar is made dutiable at \$1 per ton in the Fordney bill. The duty asked is \$2 per ton on crude and \$6 per ton on the ground or manufactured product.

Fluorspar, in the Fordney bill, takes a duty of \$5 per ton for the first year after the passage of the bill, after which it is to be dutiable at \$4 per ton. The domestic industry asks that the rate of duty be \$6 per ton on material running 80 per cent CaF_2 or better.

Among the other items that are being hard fought is gypsum. The Fordney bill provides a duty of 25c. per ton on the crude material, \$1.40 per ton on ground or calcined gypsum, 8c. per 100 lb. on white portland cement and from \$3.50 to \$14 per ton on Keene's cement.

Farmers to Demand Free Fertilizers

Headed by the Farm Bureau Federation, all the agricultural organizations maintaining headquarters in Washington are uniting in a drive on proposed duties on fertilizer materials. Potash and sulphate of ammonia are made dutiable in the bill that passed the House. Pyrites is on the free list of the Fordney bill, but an effort is being made to have the Senate committee amend the bill so as to provide a duty of \$4 a ton on this material.

The agricultural organizations are preparing their case with great care. A report and recommendations in the matter will be prepared by the Finance Committee and also will be placed in the hands of the agricultural bloc in both the Senate and in the House.

Oil Claims Staked During Winter at Fort Norman

When the first steamboat arrived at Fort Norman it was found that about 700 miles of territory along the Mackenzie River had been staked during the winter months. It appears that half-breeds have been spending the winter staking ground, which they were anxious to transfer to the first comers at a small consideration. Much of this ground is said to have been staked inaccurately, and it is feared there will be found to be considerable overlapping and general confusion that will lead to considerable litigation.

To Develop Sulphur Deposits

The Texas Co., Houston, Tex., is developing plans for the utilization of its sulphur properties in Mexico, totaling about 28,000 acres of land. The property is rich in deposits of this material and it is said that preliminary surveys indicate that it can be mined at a cost closely approximating \$3 a ton, as compared with a present market price of from \$14 a ton and upward for crude material, according to location. It is said that a subsidiary company will be organized to carry out the proposed development.

Stock Promotion and Potash in West Texas

To protect the public from misrepresentation and fraud by unscrupulous promoters and sellers of stocks based on potash deposits in western Texas the United States Geological Survey states that the potash deposits there, instead of being 1,100 or even 300 ft. thick, as represented by the promoters, have not yet been proved to be of workable thickness or of commercial value. Rich potash salts, comprising the mineral polyhalite, which were deposited in association with great thicknesses of rock salt and gypsum in "red beds," as in Germany and in fact at the same time as the German deposits, have been discovered by representatives of the Geological Survey and the Texas University Bureau of Geology and Technology in a co-operative search, but though this discovery, which was made public early in June, is encouraging and interesting, the practical question whether the deposits are thick enough to mine—that is, whether they are worth anything—is yet to be answered.

The results of the tests of the borings from three wells, of which those that are farthest apart are distant from each other about 125 miles, are certainly encouraging, but the Government geologists warn the public that the conditions of drilling and sampling at all three points are so unsatisfactory that it still remains to be seen whether the beds that are rich in potash are thick enough to justify their commercial exploitation. Considerable drilling, including wells in new areas, as well as careful examination, will evidently be necessary to determine the thickness of the potash deposits in any of the areas with the accuracy necessary for sound commercial computations. The potash content of the salts must of course also be taken into consideration. Some other area in the "red beds" region not yet drilled or not properly tested if drilled is likely to contain the maximum thickness of potash deposits. Drill cores are needed instead of the unsatisfactory samples brought up by the bailer, or, worse yet, washed up by the rotary rig without means of accurate determination of the actual thickness of the layer of potash or of its exact depth. Thorough tests with the core drill are justified by the tremendous importance to the whole United States of the discovery of commercial deposits of potash in this region—a discovery of far greater value than that of an oil pool.

T.A.P.P.I. Meeting Postponed

At a meeting of the executive committee of the Technical Association of the Pulp and Paper Industry held Sept. 15, it was decided to cancel the proposed fall meeting at Washington and other points, Oct. 18 to 21. Owing to conditions in the paper industry, it was considered advisable to postpone this joint meeting of T.A.P.P.I. and the American Pulp and Paper Mill Superintendents' Association until some time in 1922.

SECRETARY'S OFFICE NOW WITH A.P.P.A.

The office of the secretary has been removed from 542 Fifth Ave. to the general offices of the American Paper and Pulp Association, 18 East 41st Street, New York, where quarters have been provided on the sixth floor by Executive Secretary Baker.

Japanese to Manufacture Synthetic Ammonia Under Claude Process

A Japanese company has just taken up an option for the manufacture of synthetic ammonia under the Claude process, according to a cable dispatch from Lyons, France. Under the terms of the option the Nipponese firm will pay 7,000,000 f. to the Société de L'Air Liquide.

An English group is also negotiating with the French society for the purchase of a license, for which not less than 10,000,000 f. will be paid.

Britain Removes Embargo on Export of Sulphate of Ammonia

The Board of Trade has lifted the embargo on the export from England of sulphate of ammonia, according to a cable dispatch from London.

Book Reviews

THE JOURNAL OF THE INSTITUTE OF METALS, Vol. XXV. Cloth, pp. xiv+522, with 27 plates, 8vo. Edited by G. Shaw Scott, M.Sc. 1921. London: Institute of Metals, 36 Victoria St., S.W.1. Price 31s. 6d. net.

This book contains papers and discussions presented before the annual meeting held in London during March, 1921 (publication committees of American Engineering Societies please notice the date), and, in addition, 120 pages of closely set type containing abstracts of current literature relating to non-ferrous metals and industry. The latter section has become especially important and must represent a great deal of painstaking labor on the part of the half dozen metallurgists who are responsible for the work. No less than 150 publications are regularly examined, from which about 300 articles have been abstracted. Members of the Institute have the privilege of obtaining separate reprints of all these abstracts, printed on one side of the paper only and suitable for separate filing, for a small sum of money.

A paper by Moore, Beckinsale and Mallinson on "Season Cracking of Brass and Other Copper Alloys," together with a voluminous discussion, occupies 115 pages in the book. This paper was abstracted at length in CHEMICAL & METALLURGICAL ENGINEERING, June 1, 1921 (vol. 24, p. 976). A contribution by P. H. Brace, "Some Notes on Calcium," was also reprinted July 20, 1921 (vol. 25, p. 105).

Another paper which created a great deal of discussion was by Prof. Carpenter and Miss Elam, continuing their observations on recrystallization and grain growth. John L. Haughton, of the National Physical Laboratory, also completed the presentation of his very painstaking and accurate work on the copper-tin equilibrium diagram.

E. E. THUM.

* * *

THE WORLD'S CHEMICAL INDUSTRY AND TRADE, 1913-14 TO 1919-20. By Dr. W. A. Dyes. Vol. I, Edition E. xx+752 pp. 1921. Hopf'sche Verlagsbuchdruckerei, Gebr. Jenne, Wittenberg, near Halle, Germany. Price, \$5.

Dr. Dyes has felt the need for a yearly international handbook in which to place before the readers abstracts of the literature published in leading periodicals and trade papers of the world on subjects dealing with the economic phases of the chemical industries. With this in view he has compiled the first volume of such a work in which the period from 1913 to September, 1920, has been covered. The abstracts are, more correctly speaking, extracts, since they are paragraphs lifted bodily from the original articles; the book is thus a compilation of clippings from literature published mainly in German and English. Articles published in other languages are condensed, as a rule, into a few lines of German.

An English index of subject matter, an arrangement of main text in German, English and French, a list of some individuals and firms, and finally an index by countries occupy pp. vii to xx. The main text, pp. 1-669, is arranged in alphabetical order with subject headings in German, English and French. Pages 670 to 752 contain an alphabetical list of 461 German companies (Aktiengesellschaften), 1,548 German corporations (G.m.b.H.), 773 British and 561 French companies.

The compilation shows that the selection of the material has been both careful and comprehensive. With the exceptions of the references taken from English literature, however, the handbook will not be of much tangible use to those readers who are not familiar with the German language.

After a general survey of the great mass of subject matter covered it is evident that Dr. Dyes has succeeded in compiling a book which will prove useful to those who wish to obtain information on the economic status of chemical products or on what he calls the "new science of chemistry."

Personal

Lieutenant H. B. BRAMLET, Chemical Warfare officer at Camp Meade, has been transferred to Edgewood Arsenal.

Dr. J. B. BROWN is to do research, with Prof. Richards, in the pharmacology department of the University of Pennsylvania.

Dr. A. W. DAVISON has been appointed professor of chemistry at the Rensselaer Polytechnic Institute, succeeding Prof. A. T. Lincoln, who has resigned to join the faculty of Carlton University, Minnesota. Captain Davison was professor of physical and electrochemistry at the University of Cincinnati previous to the war; he entered the Chemical Warfare Service and was in charge of the 50-ton mustard gas plant at Buffalo. For the last two years he has been directing research work for the Virginia Haloid Co.

Dr. C. G. DERICK has severed his connection as chief of research of the National Aniline & Chemical Co. and has organized the company of C. G. Derick & Co., Buffalo, N. Y., and will engage in consulting work and special research.

CARL F. DIETZ, vice-president and sales manager of the Norton Co., Worcester, Mass., has resigned to become president and general manager of the Bridgeport Brass Co., Bridgeport, Conn., which position he assumes Oct. 1.

Major G. M. HALLORAN has been transferred from the infantry to the Chemical Warfare Service. Major Halloran was an instructor in the infantry service school at Camp Benning. He will be assigned to similar duties with the Chemical Warfare Service.

Dr. HARRY F. LEWIS, formerly of the research laboratory of the National Aniline & Chemical Co.'s Buffalo works, recently resigned and is now assistant professor in charge of physical chemistry at Cornell College, Iowa.

Dr. ERNEST E. LYDER, who received his Ph.D. degree at Columbia University last June, has joined the Catlin Shale Oil Co. of Elko, Nev., as refinery engineer. Dr. Lyder was formerly with the H. L. Doherty company.

Major W. N. PORTER has been transferred from the Coast Artillery to the Chemical Warfare Service. He will serve in the administration section.

Major A. L. ROCKWOOD has taken up duties in the supply division of the Chemical Warfare Service.

J. J. WARD has been appointed manager of Carrolton, Mich., plant of the Michigan Sugar Co., succeeding Frank D. Ewen, resigned. Mr. Ward has been connected with the Caro, Mich., works of the company for some time past.

DAVID WHITE, chief geologist of the U. S. Geological Survey, left Washington on Sept. 4, for an extended field trip, during which he will examine reported oil-shale deposits in the northern Appalachian region and will make several stratigraphic studies in the Pennsylvania system.

Obituary

LLOYD W. CHAPMAN, formerly Western editor of CHEMICAL & METALLURGICAL ENGINEERING, died very suddenly of spinal meningitis at his home in Berkeley, Cal., Sept. 6, 1921. He leaves a widow and two children. Mr. Chapman was born in Pepperell, Mass., thirty-four years ago, and was graduated from Amherst Agricultural College. He specialized in chemistry, and this, with a desire to grow up in the West, led him to accept a position as chemist in the laboratory of the Boston & Montana smelter at Great Falls, Mont.—now one of the plants belonging to the Anaconda company. His rise was steady, and when the war broke out he was acting as technical assistant to the superintendent of the large electrolytic copper refinery at that place. He then entered the employ of the du Pont company, and was assigned to work on the extensions to the smokeless powder

plant at Penns Grove, N. J. On completion of construction, he was made superintendent of the alcohol and ether department, a position he filled with signal success. When operations were curtailed after the armistice, Mr. Chapman was transferred to the research department and was given several problems in solvent recovery. The solution of one of these involved the design and construction of an entirely new machine for the manufacture of imitation leather, a machine which was installed at the Newburgh plant and surpassed expectations. A desire to enlarge his outlook and to get back in the West led him about two years ago to accept the position of Western editor of CHEMICAL & METALLURGICAL ENGINEERING, to be stationed in San Francisco, and about ten months ago he was transferred to the *Journal of Electricity and Western Industry*, a McGraw-Hill publication, published in that city. Mr. Chapman's business acquaintances will regret the passing of a man of particularly sound technical ability, and his many personal friends will mourn the death of a true gentleman.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Sept. 19, 1921.

Business in heavy chemicals has shown a steady expansion during the past week, although activity in general is somewhat irregular. Buyers are becoming more confident of the firmness of price levels and are gradually increasing their stocks as consuming demand for their products increases. Buying is still of a conservative character, but individual transactions are gradually increasing and if the stability of prices is maintained, large operation should take place in the near future. Conditions that have persistently hampered trading during recent months seem to be showing signs of clearing up. Increased inquiries from home and foreign buyers are convincing that the last quarter of the year will make the most satisfactory showing. Mexico, South America, Japan and northern Europe are buying chemicals. German prices are firmer in spite of the recent slump in exchange rates, and it is expected that the recovery from this slump will force German exporters into a much firmer position, which will be reflected in prices here. English exchange is somewhat weaker, but prices named for English chemicals for import have not fallen; on the contrary, they are showing signs of greater firmness.

Among the week's developments was a stronger tone to the prussiate of soda market and an advance in prices at the close. Caustic potash also showed a tendency to work upward. Caustic soda continued firm without revealing much price change. Soda ash was somewhat weaker, with imported material a disturbing influence. Bleaching powder was in good request and higher on spot. In general, it may be stated that with the bottom practically struck in every important industry, the greatest era of expansion is plainly seen ahead by some of our leading captains of industry.

CHEMICALS

Imported 88-92 per cent caustic potash on spot has shown a stronger tendency during the week and offerings were not as free as noted a month ago. Continued heavy buying, principally by soapmakers, has absorbed a large portion of the available foreign material. Reports were also current that production abroad has been restricted on account of the low prevailing prices. At the close 4½c. per lb. was considered an inside price for goods ex-store, with sellers generally quoting 4½@4¾c. September shipment was quoted at 4½c. per lb., c.i.f. New York. Sales of imported chlorate of potash were reported during the week at 7½c. per lb. Shipments of foreign material were offered at 5½@6c. per lb., duty paid. Domestic producers reported no change in their prices from the 12c. level, f.o.b. works. Yellow prussiate of potash sold in a small way on spot at 20c. per lb. Sellers quoted the market at 20@21c. per lb. The red variety has not shown much activity during the past few days and the market is more or less nominal at

28c. per lb. Odd lot sales of *bichromate of soda* were recorded during the week at 7½@8c. per lb. The movement has been chiefly in small lots and the general quotation is 7½c. Supplies do not seem to be large, but the conservative character of buying at present is not sufficient to lift the market above its present level. *Solid caustic soda* is quoted at \$3.90@\$4 per 100 lb., although large sellers assert that the market is drifting nearer to the 4c. per lb. level. Small-lot sales have taken place at 4c. both for domestic and export use. Moderate inquiries continue to reach the market for export shipment. Producers' prices are repeated at 3½c. per lb., basis 60 per cent, f.o.b. works..

Importers of *barium nitrate* are weaker on this item and quote 7½@10c. per lb., according to quantity. Prices of imported *barium chloride* tend weaker, although still quoted at former levels of \$45@\$46 per ton. Arrivals are quoted below these figures. Other barium salts share in the weakness. Continued inactivity has forced further weakness in *white arsenic* prices, which are quoted at 6@6½c. per lb. *Red arsenic* is held firmly at 11@12c. per lb. The demand for *alums* has been fairly well sustained and prices are quite firm at recent quotations. *Lump ammonia alum* is quoted at 3½@3¾c. per lb. and *lump potash* at 3¾@4½c. Continued inquiry for *prussiate of soda* on the spot market and the relatively low supplies have been factors instrumental in bringing about a higher market for this chemical. Sales were reported late in the week up to 12½c. per lb., ex-store. At the close most dealers refused to shade 12¾c. Foreign shipments were quoted at 11¾c. per lb., c.i.f. New York. Prices on *formaldehyde* during the week have covered a range extending from 12@12½c. per lb. in barrels. Producers were able to place some business at the inside figure, f.o.b. works. The demand has shown a little more activity than noted a week ago. Spot *oxalic acid* is quoted at 16@17c. per lb., depending upon the brand and quantity. Irregular prices on *tartaric acid* are heard in the open market for imported material and the range extends from 25@26c. per lb. for crystals. The powdered variety is moving at 27@28c. per lb. Domestic material is being held at 35c. per lb., with small-lot trading through the regular consuming channels featuring. Buyers are not showing any unusual interest at present and the movement is mostly of a routine jobbing nature.

Business in *copper sulphate* is fair for this season of the year. August trade did not average up to a year ago. Inquiries are reaching the market for September shipment and it looks as though this month will prove satisfactory from a trade standpoint. There is a fair general demand from the textile, railroad and other consuming industries. Occasional sales go through for export to South America, but the abnormally low prices named for goods by foreign sellers is preventing European business. It is admitted that quite a bit of business for Italy and France could be placed if the price were low enough. Quotations are generally 5½c. per lb. or higher, but imported sulphate is offered in limited amounts as low as 5c. per lb. Lower prices are named in most quarters on *soda ash*, as the demand has been satisfied by imported material. Spot resale prices are lower at \$2 per 100 lb. Prices on imported *permanganate of potash* are lower at 22@24c. per lb., according to seller and quantity.

COAL-TAR PRODUCTS

Increased activity is noted in all branches of the coal-tar products market. Business during the past ten days has been picking up rapidly and buyers are entering the market more freely than at any time this year. The attitude of Congress seems to have had a great deal to do with the change, as the trade in general is coming to believe more firmly that the Fordney tariff bill will include protection of adequate nature when it is ultimately passed. The market is rapidly being relieved of the great resale surplus stocks that were available. Renewed activity in the textile industry is resulting in a better inquiry for dyestuffs and while large contract business has not developed as yet, there is a broader inquiry for small lots, showing that many mills are short of supplies. Refiners of *benzene* are quoting 27@33c. per gal. for future delivery. Spot supplies are scarce and odd lots command a premium, with some small sales recorded as high as 40c. per gal. Practically

no improvement in coke-oven operations has been made, and as a consequence no great relief can be expected for some weeks to come. Production at present is about 20 per cent normal. Some odd lots of *phenol* have sold at 8@8½c. per lb., but most prime goods are held at 9@9½c. on spot. Competition is keen and stocks are still large. *U.S.P. benzoic acid* is quoted at 70c. per lb. and technical at 50@60c., depending upon seller and quantity. Considerable activity is noted in the U.S.P., with the canneries taking the major part of the output.

Offerings of *aniline oil* as low as 18c. per lb. have been made by factors, with 20c. quoted in other directions. Resellers have made sales down to 17½c. per lb. The tone of the market is weak and some producers are showing a strong desire to liquidate their stocks. Supplies are more than sufficient to take care of the present moderate demand. Makers of *beta naphthol* quote up to 40c. per lb., but on actual business 32c. is the price usually named. Stocks are unusually large and the demand is far from active. Some producers are desirous of realizing cash on their holdings and are shading prices in an attempt to stimulate business. Resellers are quoting 32c. per lb., with a few odd lots recorded as low as 30c. The present prices are said to be below the cost of production and one prominent factor is said to have stopped producing and is supplying his customers from the open market.

Manufacturers of *dimethylaniline* quote 45c. per lb. and upward, depending upon the quantity and seller. The resale market is pegged at 42c. The demand is moderate and shows signs of slight improvement.

The St. Louis Market

ST. LOUIS, Sept. 16, 1921.

While there has been a steady improvement in activity in the drug and fine chemical market, with spot orders being more frequent, it must be granted that the expectations of two months ago have not been fulfilled. It seems that this year there will be no definite demarcation between the summer lull and the fall increase in activity as in former years, but that the improvement will be slow but steady. No further declines to any extent are looked for, as most items are down to prices based on actual costs, and a few are even being offered below the cost of production. The market on heavy chemicals maintains its improvement, with several chemicals enjoying a very strong demand.

ALKALIS

Caustic soda demand continues good and the price of \$4 per 100 lb., basis 73-75 per cent solid, f.o.b. point of production, is very firm. *Soda ash* demand is only fair, with manufacturers' schedule prevailing. *Bicarbonate of soda* and *sal soda* are in light demand, with the former holding at \$2.60@\$2.75 per 100 lb. in less than carlots.

INDUSTRIALS

Carbon bisulphide is scarce, with a very active demand for substantial quantities. The grain elevators are beginning to call for this and also *carbon tetrachloride* to combat the weevil. *Sulphur* is in fair demand, with price of \$2.10 per 100 lb. for the commercial in bags.

CHEMICALS, DRUGS, PHARMACEUTICALS

The demand for *bismuth salts* continues to be very active. *Cream of tartar* is in routine demand. *Ether* demand shows signs of activity, and *motor ether* is beginning to move in anticipation of the winter demand. *Iodides* have increased steadily in demand, and the same holds true for *sodium benzoate*. Prices on the above remain unchanged. *Caffeine alkaloid* is very weak. *Zinc stearate* has been enjoying an excellent demand. *Glycerine* has reacted from its low point of 14c., and now holds at 14½c. per lb., spot and contract, with routine demand.

ACIDS

Sulphuric acid demand is light. Several manufacturers have stopped production temporarily, and are taking care of orders from storage stocks. *Citric acid* demand is light, with price unchanged. *Tartaric acid* is in routine demand. *Pyrogallie* and *benzoic acids* are both having an active demand and good movement. There is a good demand for

the U.S.P. *carbolic acid*, while the large Government stocks still affect the technical, and demand on the latter is light. *Phosphoric acid* demand is routine.

VEGETABLE OILS

Linseed oil rose to a maximum of 80c. per gal. before resuming its present price of 78c., basis raw in barrels, ex-warehouse. Most of the demand is for spot oil. *Castor oil* continues in very good demand, with price firm at 11½c. per lb. in drums for No. 1 U.S.P. *Turpentine* demand is routine and the price has advanced to 69c., basis barrels ex-warehouse.

The Iron and Steel Market

PITTSBURGH, Sept. 16, 1921.

There has been no material increase in the past week in the total volume of demand upon the steel mills, but the improvement previously recorded has been held.

Demand is still so light by comparison with productive capacity that the relative increase in demand may be overlooked. A plain distinction must be made between the actual consumption of steel and the demand upon the mills, resulting in production and shipments. On account of the existence of stocks of steel in the hands of buyers, and of finished wares made from steel, the demand upon the mills fell far below a normal relation to the general business activity of the country.

Production constitutes an immediate reflection of the volume of demand, since all buying is of hand-to-mouth character and for the quickest delivery possible. In both sheets and tin plates production is at nearly 45 per cent of capacity, and the tin plate showing is particularly remarkable because normally the fore part of September is approximately the duller period of the year in tin plate. Pipe mills are operating at about 40 per cent, while wire mills are operating at about 50 per cent on an average. Bar production is at a lower rate, while production of plates, shapes and rails is very small.

STEEL PRICES

In view of the continued decline in steel prices for so many months, it was rather spectacular that wire products should advance in price but an advance of \$2 a ton in plain wire and \$3 a ton in barb wire and nails became a fact this week, the American Steel & Wire Co. (Steel Corporation) making the advance effective Monday, Sept. 12, while the independents followed. The new prices are: Plain wire, 2.60c.; galvanized wire, 3.10c.; painted barb wire, 3.05c.; galvanized barb wire, 3.55c.; cement coated nails, \$2.50; wire nails, \$2.90. An advance in wire prices, however, is not like an advance in steel prices in general.

Bars, shapes and plates are perhaps a shade easier than a week ago, 1.65c. being a more common price, while prices below that, possibly even below 1.60c., are reported as done on especially desirable orders. Sheets remain firm at 2.75c. for black and 3.75c. for galvanized. Two large independent mills, one in the Mahoning Valley and one in the Chicago district, have announced an advance in their prices of \$5 a ton, to 3c. and 4c. respectively, but in view of the strenuous competition it seems improbable that an advance of this size will be followed generally.

Prices on tubular products developed early in July were promptly shaded as to oil country goods, but held fairly well until recently as to standard steel pipe. The prospect now is that there will be a formal reduction in recognition of the shading, to a level that may hold.

Generally speaking, it is plain that finished steel prices on an average are very near their bottom with present wage rates and freight rates.

PIG IRON AND COKE

Pig iron inquiry is very light, but the little burst of activity recently may be repeated, as there was no forward buying. The market remains quotable at \$20 for bessemer, \$19 for basic and \$21 for foundry, f.o.b. valley furnaces.

Connellsville furnace coke is firm at \$3.25, with not much to be had at that level. A fortnight ago the market was \$2.90@3.

General Chemicals CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.12 - \$0.12	\$0.40 - \$0.45

Molybdic, C. P.....lb.	4.00 - 4.50	4.50 - 5.00
Muriatic, 20 deg. (see hydrochloric).....lb.	0.61 - 0.62	0.07 - 0.07
Nitric, 40 deg.....lb.	0.07 - 0.07	0.07 - 0.07
Nitric, 42 deg.....lb.	0.16 - 0.16	0.17 - 0.18
Oxalic, crystals.....lb.	1.13 - 1.13	1.14 - 1.18
Phosphoric, 50 per cent solution.....lb.	1.20 - 1.25	2.7 - 3.5
Picric.....lb.	1.25 - 1.90	1.75 - 1.90
Pyrogallol, resublimed.....lb.	11.75 - 13.00	13.00 - 15.00
Sulphuric, 60 deg., tank cars.....ton	18.00 - 20.00	22.50 - 23.00
Sulphuric, 60 deg., drums.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., tank cars.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., drums.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, fuming, 20 per cent (oleum) tank cars.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, fuming, 20 per cent (oleum) drums.....ton	23.00 - 23.50	24.00 - 24.50
Sulphuric, fuming, 20 per cent (oleum) carboys.....ton	31.00 - 32.00	33.00 - 34.00
Tannic, U. S. P.....lb.	0.45 - 0.48	0.75 - 0.85
Tannic (tech.).....lb.	0.45 - 0.48	0.50 - 0.55
Tartaric, imported crystals.....lb.	0.25 - 0.26	0.25 - 0.26
Tartaric acid, imported, powdered.....lb.	0.27 - 0.28	0.27 - 0.28
Tartaric acid, domestic.....lb.	0.27 - 0.28	0.27 - 0.28
Tungstic, per lb. of WO.....lb.	1.30 - 1.40	1.30 - 1.40
Alcohol, Ethyl.....gal.	4.65 - 4.90	4.65 - 4.90
Alcohol, Methyl (see methanol).....gal.	3.5 - 3.6	3.5 - 3.6
Alcohol, denatured, 188 proof.....gal.	3.7 - 3.8	3.7 - 3.8
Alcohol, denatured, 190 proof.....gal.	0.31 - 0.32	0.31 - 0.32
Alum, ammonia lump.....lb.	0.03 - 0.04	0.04 - 0.04
Alum, potash lump.....lb.	0.03 - 0.04	0.04 - 0.04
Alum, chrome lump.....lb.	1.10 - 1.11	1.11 - 1.12
Aluminium sulphate, commercial.....lb.	0.02 - 0.02	0.02 - 0.02
Aluminium sulphate, iron free.....lb.	0.03 - 0.03	0.03 - 0.04
Aqua ammonia, 26 deg., drums (750 lb.).....lb.	0.07 - 0.07	0.08 - 0.08
Ammonia, anhydrous, cyl. (100-150 lb.).....lb.	0.30 - 0.32	0.33 - 0.35
Ammonium carbonate, powder.....lb.	0.07 - 0.07	0.08 - 0.09
Ammonium chloride, granular (white sal ammoniac).....lb.	0.06 - 0.06	0.06 - 0.07
Ammonium chloride, granular (gray sal ammoniac).....lb.	0.06 - 0.07	0.07 - 0.08
Ammonium nitrate.....lb.	0.07 - 0.07	0.07 - 0.08
Ammonium sulphate.....100 lb.	2.20 - 2.25	2.30 - 2.40
Amylacetate.....gal.	3.25 - 3.50	3.25 - 3.50
Amylacetate tech.....gal.	2.50 - 3.00	2.50 - 3.00
Arsenic oxide, (white arsenic) powdered.....lb.	0.06 - 0.06	0.06 - 0.07
Arsenic, sulphide, powdered (red arsenic).....lb.	1.11 - 1.11	1.12 - 1.13
Barium chloride.....45.00 - 46.00	47.00 - 50.00	47.00 - 50.00
Barium dioxide (peroxide).....lb.	0.20 - 0.21	0.22 - 0.23
Barium nitrate.....lb.	0.07 - 0.08	0.08 - 0.09
Barium sulphate (precip.) (blanc fixe).....lb.	0.04 - 0.04	0.04 - 0.05
Bleaching powder (see calc. hypochlorite).....		
Blue vitriol (see copper sulphate).....		
Borax (see sodium borate).....		
Brimstone (see sulphur, roll).....		
Bromine.....lb.	0.27 - 0.28	0.28 - 0.30
Calcium acetate.....100 lbs.	2.00 - 2.05	2.00 - 2.05
Calcium carbide.....lb.	0.04 - 0.04	0.05 - 0.05
Calcium chloride, fused lump.....ton	23.50 - 24.00	24.50 - 25.50
Calcium chloride, granulated.....lb.	0.01 - 0.02	0.02 - 0.02
Calcium hypochlorite (bleach powder) 100 lb.	2.75 - 2.80	2.90 - 3.50
Calcium peroxide.....lb.	1.40 - 1.50	1.40 - 1.50
Calcium phosphate, tribasic.....lb.	0.15 - 0.16	0.15 - 0.16
Camphor.....lb.	0.70 - 0.73	0.70 - 0.73
Carbon bisulphide.....lb.	0.06 - 0.06	0.06 - 0.07
Carbon tetrachloride, drums.....lb.	1.10 - 1.10	1.11 - 1.12
Carbonyl chloride (phosgene).....lb.	0.60 - 0.60	0.60 - 0.75
Caustic potash (see potassium hydroxide).....		
Caustic soda (see sodium hydroxide).....		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	0.08 - 0.09	0.09 - 0.10
Chloroform.....lb.	0.38 - 0.43	0.38 - 0.43
Cobalt oxide.....lb.	2.00 - 2.10	2.00 - 2.10
Copperas (see iron sulphate).....		
Copper carbonate, green precipitate.....lb.	0.19 - 0.19	0.20 - 0.21
Copper cyanide.....lb.	0.50 - 0.62	0.50 - 0.62
Copper sulphate, crystals.....lb.	0.05 - 0.05	0.05 - 0.06
Cream of tartar (see potassium bitartrate).....		
Epsom salt (see magnesium sulphate).....		
Ethyl Acetate Com. 85%.....gal.	1.00 - 1.10	1.00 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....lb.	1.12 - 1.12	1.40 - 1.42
Formaldehyde, 40 per cent.....lb.	3.25 - 3.75	3.25 - 3.75
Fusel oil, ref.....gal.	1.50 - 1.75	1.50 - 1.75
Fusel oil, crude.....gal.	1.41 - 1.41	1.41 - 1.41
Glauber's salt (see sodium sulphate).....		
Glycerine, C. P. drums extra.....lb.	3.50 - 3.60	3.50 - 3.60
Iodine, resublimed.....lb.	1.10 - 1.20	1.10 - 1.20
Iron oxide, red.....lb.	18.00 - 19.00	20.00 - 21.00
Iron sulphate (copperas).....ton	10.1 - 10.1	10.1 - 10.1
Lead acetate.....lb.	0.09 - 0.09	0.10 - 0.11
Lead arsenate, paste.....lb.	0.15 - 0.20	0.15 - 0.20
Lead nitrate.....lb.	0.07 - 0.08	0.08 - 0.09
Litharge.....lb.	1.30 - 1.40	1.30 - 1.40
Lithium carbonate.....lb.	0.08 - 0.08	0.09 - 0.10
Magnesium carbonate, technical.....lb.	2.50 - 2.75	3.10 - 3.75
Magnesium sulphate, U. S. P.....100 lb.	1.10 - 1.10	1.10 - 1.10
Magnesium sulphate, technical.....100 lb.	0.66 - 0.68	0.66 - 0.68
Methanol, 95%.....gal.	0.70 - 0.72	0.70 - 0.72
Methanol, 97%.....gal.	0.12 - 0.12	0.12 - 0.12
Nickel salt, double.....lb.	0.14 - 0.14	0.14 - 0.14
Nickel salt, single.....lb.	0.40 - 0.41	0.42 - 0.45
Phosgene (see carbonyl chloride).....		
Phosphorus, red.....lb.	0.30 - 0.35	0.30 - 0.35
Phosphorus, yellow.....lb.	1.11 - 1.11	2 - 1.12
Potassium bichromate.....lb.		

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . \$. . .	\$0.28½ - \$0.29½
Potassium bromide, granular..... lb.		.16 - .25
Potassium carbonate, U. S. P..... lb.	.35 - .40	.45 - .50
Potassium carbonate, 80-85%..... lb.	.05 - .05½	.06 - .06½
Potassium chlorate, crystals..... lb.	.07 - .07½	.07½ - .10
Potassium cyanide..... lb.		.26 - .28
Potassium hydroxide (caustic potash)..... lb.	.04½ - .04¾	.05 - .06
Potassium muriate, 80% K.C.L..... ton	42.50 - 45.00	
Potassium iodide..... lb.		2.75 - 3.00
Potassium nitrate..... lb.	.09½ - .09¾	.10 - .12½
Potassium permanganate..... lb.	.22 - .23	.24 - .25
Potassium prussiate, red..... lb.	.28 - .29	.29½ - .30
Potassium prussiate, yellow..... lb.	.20 - .20½	.21 - .22
Potassium sulphate (powdered)..... per unit		1.20 - 1.25
Rochelle salts (see sodium potas tartrate).....		
Salammoniac (see ammonium chloride).....		
Sal soda (see sodium carbonate).....		
Salt cake (bulk)..... ton		20.00 - 25.00
Silver cyanide..... oz.		1.35 - 1.38
Silver nitrate..... oz.		.41½ - .42
Soda ash, light..... 100 lb.	2.00 - 2.10	2.15 - 2.50
Soda ash, dense..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate..... lb.	.04 - .04½	.04½ - .05
Sodium bicarbonate..... 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium bichromate..... lb.	.07½ - .08	.08½ - .08¾
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P..... lb.	.04½ - .05	.05½ - .06
Sodium borate (borax)..... lb.	.05½ - .06	.06½ - .07
Sodium carbonate (sal soda)..... 100 lb.	1.90 - 2.00	2.10 - 2.40
Sodium chl rate..... lb.	.07½ - .07¾	.08 - .08½
Sodium cyanide..... lb.	.19½ - .21	.22 - .30
Sodium fluoride..... lb.	.10½ - .11	.11½ - .12
Sodium hydroxide (caustic soda)..... 100 lb.	3.90 - 4.00	4.10 - 4.60
Sodium hyposulphite..... lb.		.03½ - .03¾
Sodium nitrate..... 100 lb.	2.10 -	2.30 -
Sodium nitrite..... lb.	.07 - .07½	.07½ - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.04½ - .04¾	.05 - .05½
Sodium potassium tartrate (Rochelle salts) lb.		.21 - .24
Sodium prussiate, yellow..... lb.	.12½ - .13	.13½ - .13¾
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02½ - .03	.03½ - .03¾
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04½ - .04¾	.05 - .06
Sodium sulphite, crystals..... lb.	.03½ - .04	.04½ - .04¾
Strontium nitrate, powdered..... lb.	.12 - .12½	.13 - .14
Sulphur chl ride, red..... lb.	.05 - .05½	.05½ - .06½
Sulphur, crude..... ton	18.00 - 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08½	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.38 - .40
Zinc carbonate, precipitate..... lb.	.16 - .16½	.17 - .17½
Zinc chloride, gran..... lb.	.09½ - .09¾	.10 - .11
Zinc cyanide..... lb.	.42 - .44	.45 - .47
Zinc dust..... lb.	.11½ - .11¾	.11½ - .12½
Zinc oxide, XX..... lb.	.07½ - .07¾	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 - \$1.20
Alpha-naphthol, refined..... lb.	1.35 - 1.40
Alpha-naphthylamine..... lb.	.35 - .40
Aniline oil, drums extra..... lb.	.17½ - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.00 - 1.25
Benzidine, base..... lb.	1.00 - 1.10
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.70 - .72
Benzoate of soda, U.S.P..... lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.32 - .35
Beta-naphthylamine, sublimed..... lb.	1.90 - 2.00
Cresol, U. S. P., in drums (100 lb.)..... lb.	.17 - .19
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .75
Cresylic acid, 35-97%, dark, in drums..... gal.	.60 - .65
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.20 - 1.25
Dimethylaniline..... lb.	.42 - .50
Dinitrobenzene..... lb.	.25 - .28
Dinitrochlorobenzene..... lb.	.25 - .30
Dinitronaphthalene..... lb.	.32 - .40
Dinitrophenol..... lb.	.37 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, car lots, in drums..... gal.	.35 - .40
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.10 - 1.20
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.50 - 1.60
Naphthalene crushed, in bbls..... lb.	.06½ - .07½
Naphthalene, flake..... lb.	.06½ - .08
Naphthalene, balls..... lb.	.08 - .09½
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.23 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.79 - .82
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50
Phenol, U. S. P., drums..... lb.	.08½ - .10
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.25 - 2.30
Salicylic acid, tech., in bbls..... lb.	.18 - .20
Salicylic acid, U. S. P..... lb.	.20 - .25
Salol..... lb.	.60 - .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.20 - \$0.21
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.36 - .42
Candelilla wax..... lb.	.25 - .26
Carnauba, Florida..... lb.	.48 - .50
Carnauba, No. 2, North Country..... lb.	.25 - .26
Carnauba, No. 3, North Country..... lb.	.15 - .15½
Japan..... lb.	.23 - .24
Montan, crude..... lb.	.05½ - .06
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03½ - .03¾
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 - .
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03½
Paraffine waxes, refined, 125 m.p..... lb.	.03½ - .03¾
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 - .04½
Paraffine waxes, refined, 133-135 m.p..... lb.	.04½ - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 - .06
Stearic acid, single pressed..... lb.	.09 - .
Stearic acid, double pressed..... lb.	.10 - .
Stearic acid, triple pressed..... lb.	.11 - .11½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.40 - 5.50
Rosin E-I..... 280 lb.	5.50 - 5.60
Rosin K-N..... 280 lb.	5.75 - 5.90
Rosin W. G.-W. W..... 280 lb.	6.60 - 7.35
Wood rosin, bbl..... 280 lb.	6.25 - .
Spirits of turpentine..... gal.	.70 - .
Wood turpentine, steam dist..... gal.	.68 - .
Wood turpentine, dest. dist..... gal.	.66 - .
Pine tar pitch, bbl..... 200 lb.	. - 7.00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	. - 11.00
Retort tar, bbl..... 500 lb.	. - 11.00
Rosin oil, first run..... gal.	.35 - .
Rosin oil, second run..... gal.	.37 - .
Rosin oil, third run..... gal.	.44 - .
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.90 -
Pine oil, pure, dest. dist..... gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 -
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.25 -
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.35 -
Pinewood creosote, ref..... gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 -
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 -
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 -
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 -

Crude Rubber

Para-Upriver fine..... lb.	\$0.16 - .17
Upriver coarse..... lb.	.09 - .09½
Upriver caucho ball..... lb.	.11½ - .12
Plantation—First latex crepe..... lb.	.14 - .
Ribbed smoked sheets..... lb.	.12 - .12½
Brown crepe, thin, clean..... lb.	.15 - .
Amber crepe No. 1..... lb.	.17 - .

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.09½ - \$0.09½
Castor oil, AA, in bbls..... lb.	.10½ - .11
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.11 - .11½
Cocoonut oil, Ceylon grade, in bbls..... lb.	.10 - .10½
Cocoonut oil, Cochon grade, in bbls..... lb.	.10½ - .11½
Corn oil, crude, in bbls..... lb.	.08½ - .08¾
Cottonseed oil, crude (f. o. b. mill)..... lb.	.08 - .08½
Cottonseed oil, summer yellow..... lb.	.10 - .10½
Cottonseed oil, winter yellow..... lb.	.10½ - .11
Linseed oil, raw, ear lots (domestic)..... gal.	.77 - .78
Linseed oil, raw, tank cars (domestic)..... gal.	.71 - .72
Linseed oil, in 5-bbl lots (domestic)..... gal.	.80 - .81

Olive oil, Denatured.....	gal.	\$1.10	—	\$1.20
Palm, Lagos.....	lb.	.07	—	.08
Palm, Niger.....	lb.	.06	—	.06
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.08
Peanut oil, refined, in bbls.....	lb.	.10	—	.10
Rapeseed oil, refined in bbls.....	gal.	.86	—	.88
Rapeseed oil, blown, in bbls.....	gal.	.90	—	.92
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	.08
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Wofford Oil Co., has plans under way for extensions and improvements in its plant to cost about \$750,000. A large portion of the work will cover the installation of equipment for gasoline production.

Georgia

COLUMBUS—The Columbus Sewer Pipe Co., manufacturer of vitrified pipe, is considering the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about \$75,000. Judson C. Buchanan is manager.

Kentucky

ASHLAND—The Norton Iron Works will commence the immediate construction of a new 2-story plant addition, 150 x 200 ft., for the manufacture of wire screen cloth and kindred products. T. M. Adams is president and general manager.

LOUISVILLE—The Progress Pressed Brick Co. has perfected plans for the erection of a 1-story addition to increase the plant capacity from about 20,000 to 45,000 bricks a day. A. P. Hildebrand is president.

Louisiana

NEW ORLEANS—The Maryland Refining Co. has broken ground for the erection of its proposed new oil refinery on site recently acquired, estimated to cost in excess of \$1,000,000 with machinery.

NEW ORLEANS—The Colonial Chemical Co. has acquired a local site and plans for the erection of a new plant. Headquarters are at Reading, Pa.

Maine

RUMFORD—Owing to labor troubles, the Continental Paper & Bag Co., is arranging for the removal of its local paper manufacturing plant to a new location. The mills will be dismantled at once.

Maryland

BALTIMORE—The United States Industrial Chemical Co., Curtis Bay, has filed plans for the erection of a new 1-story plant on Fairfield Ave. Work will be commenced at once.

Massachusetts

BELMONT—The Campbell & Wiswell Co., Boston, Mass., manufacturer of paints, varnishes, etc., has completed plans for the erection of a new 1-story, brick and reinforced-concrete plant on Hittinger St., about 60 x 90 ft.

Michigan

MONROE—The Monroe Paper Products Co. has commenced operations at its new local mill, recently completed, for the manufacture of folding boxboard and other paper products. The initial daily output will average about 75 tons, with the plant giving employment to close to 100 men. The company is said to have orders on hand to insure continuous production for an indefinite period. William R. Harris is president and Roy M. Sperry, secretary.

MONROE—The Consolidated Paper Co. has preliminary plans under way for the erection of a new mill for the manufacture of strawboard and affiliated paper products. E. C. Bauch is president.

DETROIT—The Solvay Process Co. has arranged for the resumption of production at its plant at Delray, near Detroit, following a shut-down for the past two months. The works will give employment to about 1,500 operatives for initial manufacture.

KALAMAZOO—Peter King, formerly president of the Monarch Paper Co., and associates are said to be planning for the organization of a new company, capitalized at \$20,000, for the erection of a local plant for the reclaiming of sulphite and ground wood from newspaper and other

grades of paper goods, the material to be used for the re-manufacture of paper products. The initial works will be equipped for a daily capacity of about 50 tons of material.

Mississippi

GREENVILLE—The Rainbow Oil Co., recently organized with a capital of \$500,000 by E. L. Wortham, El Dorado, Ark., and associates, has plans under way for the erection of a new oil-refining plant near Greenville.

Missouri

KANSAS CITY—The Corn Products Refining Co., 11 Battery Pl., New York, is planning for the construction of a new refinery at Kansas City. The plant will consist of a total of 16 buildings, with tanks and other miscellaneous structures, estimated to cost about \$5,000,000 with machinery. It will have an initial handling capacity of about 25,000 bush. of corn.

New Jersey

NEWFIELD—The Wilcox Durand Glass Co. is taking bids for the erection of a new 1-story plant extension, 31 x 101 ft., to be used for machine and other repair service. The W. P. Cameron Engineering Co., Witherspoon Bldg., Philadelphia, Pa., is architect and engineer.

KEASBEY—The National Fireproofing Co. has arranged for the resumption of production of hollow tile and other burned clay products, at its local plant, following a shut-down of several months' duration.

TRENTON—Fire recently destroyed a portion of the plant of the Acme Pottery Co., May and Beakes Sts., manufacturer of sanitary earthenware, with loss estimated at about \$50,000. The company is said to be planning for immediate rebuilding.

New York

NIAGARA FALLS—The Niagara Falls Felt & Paper Co., a subsidiary of the Niagara Falls Power Co., Canal Basin, has awarded a contract to the Read & Coddington Engineering Co., 238 Portage Road, for the erection of a new local plant, estimated to cost about \$300,000, including equipment.

TONAWANDA—Fire, Sept. 7, destroyed a plant portion of the plant of the Frontier Mfg. Co., Erie Ave., manufacturer of oil products, with loss estimated at about \$35,000.

Ohio

DAYTON—The Refiners Oil Co. has awarded a contract to the Dayton Asphalt Roofing Dayton, for the erection of a new 1-story plant on South Ludlow St., 60 x 100 ft.

TOLEDO—The Spitzer Paper Box Co., 3501 Monroe St., is planning for the erection of a new 3-story plant, 30 x 80 ft., on local site, estimated to cost about \$50,000. It will be used as an extension to the present works. George R. Rheinfrank, Gardner Bldg., is architect.

Oklahoma

HENRYETTA—The Henryetta Glass Co., recently organized with a capital of \$50,000, has acquired a local site, totaling about 2 acres, for the erection of its proposed new plant for the manufacture of globes, shades and other glassware for lighting services. H. L. Chambers is head.

Pennsylvania

PITTSBURGH—The Luzerne Cut Glass Works has resumed operations at its local plant following a shut-down of several months.

QUARRYVILLE—The Franklin Paper Bag Co., 305 Race St., Philadelphia, has plans under way for the erection of a new local plant about 50 x 75 ft., for the manufacture of its general line of paper products.

NEWCASTLE—The Universal Sanitary Mfg. Co., manufacturer of sanitary earthenware and other pottery products, is arranging for the immediate resumption of operations at its plant, following a shut-down

for a number of months past. The works will give employment to about 250 men.

DU BOIS—The Pittsburgh Lens Glass Co., Pittsburgh, will make a number of improvements and extensions at its plant at Falls Creek, remodeling certain portions of the works. It is planned to place the factory in operation at an early date.

DU BOIS—The Reliance Glass Co. will resume active production at its local plant at an early date, giving employment to about 250 men. Operations have been curtailed for a number of weeks past.

PHILADELPHIA—The Franklin Sugar Refining Co., South Orianna St., has awarded a contract to J. W. Paxson, 1021 North Delaware Ave., for the construction of a new building at its plant at Algon and Luzerne Sts., estimated to cost about \$85,000. The company will also make extensions and improvements in its power house at Reed and Meadow Sts. to cost about \$20,000.

NEW HOPE—The American Clay Products Co. is planning for the early operation of its new local plant, now in course of construction, for the manufacture of bricks. It is proposed to develop an initial output of about 250,000 vitrified bricks per day, and which amount will be increased at a later date. The plant will cost in excess of \$700,000.

Texas

FORT WORTH—The Texas Imperial Co., Fort Worth, is planning for the erection of a new oil refinery in the vicinity of Minerva, with initial capacity of about 100 bbl. a day.

STAMFORD—The Rule-Jayton Cotton Oil Co., recently organized with a capital of \$200,000, is planning for the erection of a large cotton oil mill on local site. C. M. Francis heads the company.

HOUSTON—The Texas Co. is arranging for the organization of a subsidiary organization for the development of sulphur properties in Mexico, comprising about 28,000 acres of land. It is proposed to establish a large production plant at the site.

SOMERSET—The Eggleston Oil Corp. is planning for the erection of a new oil refinery on local site to cost about \$60,000. It is proposed to develop an initial capacity of about 800 bbl. per day.

AMARILLO—The Plains Lubricating Co., recently organized, will operate a local plant for the production of lubricating oils. It is planned to operate on a basis of 50 drums of material per day.

Virginia

ROANOKE—The Roanoke Fiber Board Co. is completing plans for the rebuilding of its local plant, destroyed by fire last July. Bids for erection will be asked at an early date.

LYNCHBURG—The Lynchburg Glass Co. is arranging for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about \$12,000. N. D. Eller is president.

PORTSMOUTH—The Texas Co., Houston, Tex., and 17 Battery Pl., New York, N. Y., is considering the erection of a new local oil manufacturing plant.

West Virginia

BELLE—The Belle Alkali Co. will take bids at once for the erection of a new 1-story plant on local site to cost about \$50,000. A list of equipment for installation has been arranged.

Wisconsin

SHEBOYGAN—The Falls Roller Mills have had plans prepared for the erection of a new local 5-story and basement flour mill, 50 x 60 ft., estimated to cost about \$125,000. E. Gozenbach is manager.

MADISON—The Malvorine Oil Co., 815 East Main St., will make extensions and improvements in its local works on Main St., estimated to cost about \$15,000.

SHEBOYGAN—The Trelling Kiel Oil Co., Calumet Drive, has awarded a contract to Verhulst Bros., 1621 Eddle Ave., for the erection of a new 1-story and basement plant building, 50 x 150 ft., estimated to cost about \$50,000.

Mexico

TAMPICO—The Corona Oil Co. is planning for the immediate erection of the second unit of its new local refining plant, to have a daily output of about 15,000 bbl. of material per day. The company has completed the construction of the first unit of the new plant. The total cost of the plant, including pipe lines, pumping stations, etc., will be in excess of \$5,000,000.

New Companies

THE BINGOL CHEMICAL CO., 2816 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical by-products. The incorporators are J. P. Davidonis, M. Jurgelonis and Andrew J. Bloomberg.

NEWSTADT BROS., INC., Wilmington, Del., has been incorporated with a capital of \$99,000, to manufacture paints, varnishes, etc. The incorporators are Samuel, Louis and Albert Newstadt, Wilmington. Harry P. Joslyn, Ford Bldg., represents the company.

THE ANCHOR OIL CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are M. Berman, E. Weil and M. M. Sherower. The company is represented by H. Schapiro, 261 Broadway.

THE ALLYNDALE LIME CO., 235 State St., Hartford, Conn., has been organized to manufacture lime and affiliated products. W. C. Brooks, 479 West Main St., Meriden, Conn., is president; J. W. MacDonald, vice-president; and T. H. Goodrich, secretary-treasurer, 273 Washington St., Hartford.

W. N. WRIGHT, INC., Boston, Mass., has been incorporated with a capital of \$25,000 to manufacture chemicals, dyes and affiliated products. Wallace N. Wright is president; and Robert F. Wright, 212 Columbus Ave., treasurer.

THE PORTEOUS PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of \$25,000 to manufacture rubber goods. The incorporators are A. G. Porteous, F. L. Woodward and W. R. Chamberlain. The company is represented by H. C. Knoepfel, 5 Beekman St.

THE AETNA CHEMICAL CO., Newark, N. J., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are Gustave B. Feldman, S. H. Barnett and Vincent Aregena. The company is represented by Aaron Levinston, 20 Clinton St.

THE MCCARTHY FOUNDRY CO., 3307 South Lawndale Ave., Chicago, Ill., has been incorporated with a capital of \$300,000, to manufacture iron, steel and other metal castings. The incorporators are John C. Haswell, John J. Carroll and John P. Wheeland.

THE ORLANDO POTTERIES, INC., Orlando, Fla., has been incorporated with a capital of \$25,000, to manufacture china and earthenware products. M. J. Daetwyler, Orlando, is president; and G. D. Krebs, secretary-treasurer.

THE GUARD-GOOD CHEMICAL CORP., Geneva, N. Y., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are L. H. and C. F. Guard, and G. G. Goodelle. G. I. Teter, Geneva, represents the company.

THE LOS ANGELES BRASS FOUNDRY, 2052 East Vernon Ave., Vernon, Cal., has filed notice of organization to manufacture brass, bronze and other metal castings. T. J. Morgozewitz, 416 Vernon Ave., Los Angeles, Cal., heads the company.

THE VICTORY SOAP JELLY CO., Iliion, N. Y., has been incorporated with a capital of \$25,000, to manufacture soaps and affiliated products. The incorporators are A. E. H. and W. B. Loomis, Iliion. The company is represented by J. A. McFarren, Iliion.

THE GARFIELD PETROLEUM CO., Enid, Okla., has been incorporated with a capital of \$100,000, to manufacture petroleum products. J. E. Sharp, Enid, is president; and Burton E. Moore, treasurer.

THE WATERPROOF PRODUCTS CO., 56 North Eighteenth St., East Orange, N. J., has filed notice of organization to manufacture waterproofing products, chemical specialties, etc. Leon Flacker heads the company.

JOHN F. WALSH & CO., New York, N. Y., has been incorporated with a nominal capital of \$5,000, to manufacture composition products. The incorporators are J. F. and J. J. Walsh and J. J. Maier. The company is represented by C. N. Rogers, 347 Fifth Ave.

THE TRADE COMPOSITION METAL CO., 538 South Dearborn St., Chicago, Ill., has been incorporated with a capital of \$15,000, to manufacture composition metal goods and kindred products. The incorporators are Julius C. Greenbaum, William S. Newburger and Maurice C. Handelman.

THE PACIFIC COAST TIRE & RUBBER MFG. CO., Los Angeles, Cal., has been incorporated with a capital of \$2,000,000, to manu-

facture tires and other rubber products. The incorporators are William B. Wightman, W. O. Bruess and Owen C. Emery, 106-A East Broadway, Glendale, Cal.

THE NASSAU FERTILIZER & OIL CO., Fernandina, Fla., has been incorporated with a capital of \$500,000, to manufacture fertilizers, oil products, etc. J. B. Guess, Jr., is president, and W. H. Faust, secretary-treasurer, both of Denmark, S. C.

THE KEENTON CO., New York, N. Y., has been incorporated with a capital of \$10,000 to manufacture chemicals, chemical byproducts, etc. The incorporators are E. Gettlinger, L. Weisberg and S. B. Lillenstein, 280 Broadway.

THE BENJAMIN PRODUCTS CORP., Jersey City, N. J., has been incorporated with a capital of \$1,000,000, to manufacture rubber products, gutta percha specialties, etc. The incorporators are Robert A. Van Voohls, Arthur R. Oakley and William E. Schiels, Jr. The company is represented by the Registrar & Transfer, 900 Market St., Wilmington, Del.

WILLIS BROS., INC., Jersey City, N. J., has been incorporated with a capital of \$25,000, to manufacture refined oil products. The incorporators are Merwin Rosenberg, Harry W. and William C. Willis, 245 Custer Ave.

THE TRIANGLE PRODUCING & REFINING CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to manufacture petroleum products. The incorporators are John G. Clark, G. J. Knight and S. J. Bowman. The company is represented by Carnahan & Clark, 501 Investment Bldg., Los Angeles.

PERCIVAL E. FALKINGHAM, INC., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are P. E. and K. E. Falkingham, and M. D. Craig. The company is represented by L. S. Posner, 15 Broad St.

THE HYGRADE GOLD STAMPING CO., Newark, N. J., has been incorporated with a capital of \$50,000, to manufacture stamped gold and other metal stampings. The incorporators are Isadore Silberman, and Jacob Alperun, 83 Wickliffe St.

THE GENERAL ALUMINUM CO., Knoxville, Tenn., has been incorporated with a capital of \$60,000, to manufacture aluminum and other metal products. The incorporators are E. H. Hickman, F. G. Arnett and H. B. Lindsay.

THE EYERS DRUG & CHEMICAL CO., Gloucester, Mass., has been incorporated with a capital of \$25,000, to manufacture chemicals, chemical byproducts, etc. G. P. Eyers is president; and Herbert H. Eyers, 175 Western Ave., Gloucester, treasurer.

GEORGE V. GROSS & CO., INC., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture oils, extracts and affiliated products. The incorporators are G. V. and G. E. Gross, and A. Davis. The company is represented by Cohen Bros., 35 Wall St.

THE PEQUOT MFG. CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture paper products, paper boxes, etc. The incorporators are E. J. London, N. Bogin and M. L. Arnstein, 320 Broadway.

THE TRENT RUBBER CO., Trenton, N. J., has been incorporated with 10,000 shares of stock, no par value, to manufacture rubber products. The incorporators are William V. Lee, I. M. Martino and George Gildea. The company is represented by Thomas H. Thropp, Enterprise Ave.

THE MILLS-PENFIELD CORP., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture paper products. The incorporators are I. Mills, C. H. Penfield and J. Cohen, 7 West Eighth St.

THE HOPWOOD RETINNING CO., 459 Main St., Charlestown, Mass., has filed notice of organization to manufacture metal products. John A. Hopwood heads the company.

THE FLYNN SPECIALTIES CO., New York, N. Y., has been incorporated with a capital of \$200,000, to manufacture spark plugs and kindred products. The incorporators are J. F. and A. L. Flynn, and S. M. Platt, 908 Brook Ave., Bronx.

THE VACUUM FLOTATION CORP., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture chemical products. The incorporators are C. M. Chapman, C. S. Clark and C. P. Northrup, 31 Nassau St.

THE INSULATION & SPECIALTY CORP., Wilmington, Del., has been incorporated with a capital of \$500,000, to manufacture insulation products, fiber specialties, etc. The incorporators are W. L. Broman, P. C. Henning and J. L. McIntire, all of Wilmington.

Capital Increases, Etc.

THE FEDERAL CHEMICAL CO., Woodstock, Ill., has filed notice of increase in capital from \$10,000 to \$50,000.

DUNLOP AMERICA, LTD., River Road, Buffalo, N. Y., manufacturer of tires and rubber goods, has filed notice of change of name to the Dunlop Tire & Rubber Corporation of America.

THE JUNE CHEMICAL WORKS, INC., Wilkes-Barre, Pa., has filed notice of increase in capital from \$100,000 to \$250,000.

THE FISK RUBBER CO., Chicopee Falls, Mass., has arranged for a bond issue of \$10,000,000, following a merger with the Federal Rubber Co., Cudahy, Wis., and the Ninigret Co., Westerly, R. I.

THE UNITED STATES ASBESTOS CO. OF ILLINOIS, Chicago, has filed notice of increase in capital from \$25,000 to \$75,000.

THE CORTLAND GRINDING WHEEL CORP., Cortland, N. Y., has filed notice of dissolution under state laws.

THE ROSEVILLE POTTERY CO., an Ohio corporation, has filed notice of organization to operate in New York. M. T. Scott, 621 Fifth Ave., is representative.

THE WATSON-FITZGERALD CO., Danville, Va., manufacturer of bricks and other burned clay products, is arranging for an increase in capital to \$150,000.

THE APEX CHEMICAL CO., a New York corporation, has filed notice to operate in New Jersey for the manufacture of chemical products. The company is represented by H. Nelson Craig, 200 South First St., Elizabeth, N. J.

THE RIVER RAISIN PAPER CO., Monroe, Mich., has arranged for a bond issue of \$2,200,000.

Manufacturers' Catalogs

THE JEFFREY MANUFACTURING CO., Columbus, O., calls attention to Catalog 350, on Jeffrey conveying machinery, which contains illustrations, price lists and dimensions of Jeffrey chains, sprockets, conveyor and elevator details, transmission and gears.

THE ALDRICH PUMP CO., Allentown, Pa., has issued a 16-page catalog on Aldrich pumps.

THE PARKS-CRAMER CO., Fitchburg, Mass., has issued an attractive booklet on "Fluid Heat Transmission by the Merrill Process."

THE PACIFIC FOUNDRY CO., San Francisco, Cal., calls attention to a new catalog on "Corrosiron." Products made from Corrosiron, which is a high-silicon alloy, such as pipe and fittings, valves, plug cocks, plunger pumps, centrifugal pumps, etc., are illustrated and described. Specifications are also given. The physical properties are given, as well as information about the machining of Corrosiron, designs and patterns, casting, together with general information on areas and circumferences of circles, density of liquids, metric equivalents of feet and inches, conversion factors, and weights and measures.

PAWLING & HARNISCHFEGGER CO., Milwaukee, Wis., has just issued Pamphlet TX which describes and illustrates the new Skimmer Boom designed for attachment to the standard P & H 205 or 206 Excavator-Crane. The point is made that by replacing the standard boom of either of these cranes, an efficient road-grading machine is provided. In fact, this is similar to the Shovel Attachment brought out earlier this year and which is designed for use with either of the two types of P & H cranes mentioned. Data and operating cost figures on a road grading job done by William Datka, contractor, are included, together with a profile for the road, prepared by the county highway department.

THE MALCOLMSON BRIQUET ENGINEERING CO. has consolidated with the St. Louis Briquette Machine Co. under the corporate name of the Malcolmson Engineering & Machine Corp. This company acts as engineer and contractor for the building of complete plants for fuel, fuel briquetting, peat harvesting, low-temperature distillation of fuels, preparation of phosphate rock and for the drying, crushing and screening of coal and rock products. The officers of the new company are C. T. Malcolmson, president; G. Komarek, vice-president; C. E. House, secretary, and W. J. Monahan, treasurer. Offices are in the Old Colony Bldg., Chicago, Ill.

THE CALCO CHEMICAL CO., Bound Brook, N. J., has prepared some interesting data and maps showing the condition of the coal-tar dye industry in the United States in 1914 as compared with that of 1920. In 1914 there were only seven small plants in three states, employing 528 men. In 1920 there were 82 dye plants located in eighteen states, the largest employing about 4,000 men. There were also 213 coal-tar chemical plants located in twenty-five states. These conditions are cited by the Calco Chemical Co. as evidence against the presumption of a monopoly of the American dye industry.

THE PETROLEUM TRUST REFINERY, with offices in Chicago, Ill., has begun operations at the former plant of the Seven States Oil Co., Hollywood Ave., Memphis, Tenn. The plant is now running at a capacity of 800 bbl. per day, which will be increased by the end of the summer to 6,000 bbl. per day. Crude oil is being shipped in from the fields at Eldorado. B. W. Franklin is general superintendent of the Memphis plant.

THE NIAGARA RADIATOR & BAR CO., Chicago, has purchased 10 acres at the southwest corner of 83d St. and Woodlawn Ave., and is laying plans for the erection of a new foundry 140 x 175 ft. Later a 4-story warehouse will be built, making the total expenditure involved about \$250,000.

New Publications

BOOKS

SILICA AND THE SILICATES. By James A. Audley. Pp. 374; 27 illustrations. New York: D. Van Nostrand Co., 1921. Price, \$4.50.

This volume of the series on Industrial Chemistry edited by Dr. Samuel Rideal describes the silicate industries and their raw materials in the following order: silica, the many forms in which it occurs in nature; silicates and other compounds containing silica; lime, mortar and cement; the ceramic industries; glass and enamels; miscellaneous applications of silicates—alum, slag fertilizers, soils, earthy and other silicate pigments.

TECHNICAL METHODS OF ANALYSIS. Edited by Roger Castle Griffin, director of analytical department, Arthur D. Little, Inc. Pp. 666; 29 illustrations. New York: McGraw-Hill Book Co., Inc., 1921. Price, \$6.

Analytical methods which have been adopted as standard procedures in the laboratories of Arthur D. Little, Inc., have been brought together in classified form. The book covers a wide range of technical products and is supplemented by an excellent bibliography. The methods are grouped under the headings: Reagents; general inorganic analyses; general organic analyses; analysis of metals; fuels; paints and paint materials; oils, fats, waxes and soaps; wood, paper and paper-making chemicals; textiles and textile fibers; food-stuffs; miscellaneous—leather, rubber, case-hardening and cutting compounds, water, boiler scale, fertilizers, pitches, tars, cement and concrete, etc.

FAMOUS CHEMISTS: THE MEN AND THEIR WORK. By Sir William A. Tilden, F.R.S., D.Sc., LL.D., professor emeritus of chemistry in the Imperial College of Science and Technology. Pp. 296, illustrated. New York: E. P. Dutton & Co., 1921. Price, \$5.

"Among those who have supplied indispensable links in the chain of events which has culminated in the present state of knowledge in chemistry there are but few whose names are known even among well-educated people. And yet the story of their lives is full of interest and instruction for all who care about the progress of science.

"The present volume is an attempt to sketch, in a style suitable for general reading, the lives of some of the most prominent chemists of the past. As it is obviously impossible for one person to deal with them all, the first great difficulty in such a project is to make the selection. After much reflection the guiding principle adopted is the evolution of the atomic theory from the point of view of the chemist.

"The first question is, Who is to be included? A crowd of names comes at once into the mind and each man seems entitled to be called a 'great chemist'; but of those who have not been included it will be found, I believe, that however important their contribution to science their discoveries have not been indispensable along the line indicated. No disrespect is intended to any of them, but the necessity for limitation imposes a restraint which it would be easier to disregard than to comply with."

Thus the evolution of the atomic theory is traced in the lives of twenty-one chem-

ists: Boyle, Black, Priestley, Cavendish, Scheele, Lavoisier, Davy, Dalton, Gay-Lussac, Proust, Berzelius, Faraday, Avogadro, Cannizzaro, Liebig, Dumas, Frankland, Williamson, Mendeleeff, Crookes, Ramsay.

PHYSICAL CHEMISTRY FOR COLLEGES. By E. B. Millard, assistant professor of physical chemistry, Massachusetts Institute of Technology. Pp. 411; 61 illustrations. New York: McGraw-Hill Book Co., Inc., 1921. Price, \$3.50.

The more important topics of physical chemistry are treated at such length as the size of the volume allows and numerous references to recent periodical literature are included for those who would pursue any given topic further. The limitations of the orthodox laws of physical chemistry are emphasized more than is commonly done in beginning courses of physical chemistry, since it is felt that a wholesome appreciation of physical chemistry as an unfinished and growing science may stimulate thoughtfulness and research.

A TEXTBOOK OF INORGANIC CHEMISTRY FOR COLLEGES. By James F. Norris, professor of organic chemistry, Massachusetts Institute of Technology. Pp. 677; 45 illustrations. New York: McGraw-Hill Book Co., Inc., 1921. Price, \$3.50.

The subject matter is presented in a form which can be reasonably well followed by the student through private study and with the smallest amount of explanation on the part of the teacher. The subject is developed slowly and the consideration of the more abstruse material has been deferred until the student has gained some familiarity with chemical phenomena and with the language of the science.

AMERICA'S POWER RESOURCES. By Chester G. Gilbert and Joseph E. Pogue. Pp. 326; 37 illustrations. New York: The Century Co., 1921. Price, \$2.50.

This book is an attempt to interpret the special, though generally unrecognized, importance attaching to the energy resources—coal, oil, natural gas and water power; and to point to the shortcomings in the way they are handled, to which a considerable measure of our current economic difficulties is traceable. The attempt is also made to outline the changes in energy administration that are bound to come into play, if due social and industrial progress is to be attained, and to indicate the avenues of advance to which constructive efforts need to be applied. The material presented is largely the result of investigations carried on by the authors in the Smithsonian Institution, in the Fuel Administration, and in a somewhat diversified engineering practice, and brought out from time to time as special papers, emanating mostly from the Division of Mineral Technology, United States National Museum. These special contributions have attracted such notice that it seemed desirable to weld the results into this unified and less technical form for wider and more popular presentation.

AMERICAN CHEMISTRY. By Harrison Hale, Ph.D., head of department of chemistry, University of Arkansas. Pp. 215; 63 illustrations. New York: D. Van Nostrand Co., 1921. Price, \$2.

A popular treatment of the chemical industries which should be useful to the general reader and to the student as collateral reading with a course in general chemistry. The illustrations are excellent and should help the student in visualizing plant operations. References at the end of each chapter encourage further study of topics in which special interest has been aroused.

ORGANIC COMPOUNDS OF MERCURY. By Frank C. Whitmore, Ph.D., professor of organic chemistry, Northwestern University. Pp. 397. New York: The Chemical Catalog Co., Inc., 1921. Price, \$4.50.

The total amount of work which has been done on organic mercury compounds is probably greater than that done on the organic arsenicals, but it has received much less publicity. Although a number of monographs have been written in English and in German on the arsenic compounds, this is the first which has appeared in any language on the mercurials. It is number three in the American Chemical Society's series of scientific and technologic monographs.

THE WORKING OF STEEL. By Fred H. Corvin, editor, American Machinist, and K. A. Juthe, chief engineer, American Metallurgical Corporation. Pp. 245; 125 illustrations. New York: McGraw-Hill Book Co., Inc., 1921. Price, \$3.

A practical discussion of the annealing, heat-treating and hardening of carbon and alloy steel.

PHILOSOPHY AND THE NEW PHYSICS. By Louis Rougier, translated by Morton Masius, professor of physics, Worcester Polytechnic Institute. Pp. 159. Philadelphia: P. Blakiston's Son & Co., 1921. Price, \$1.75.

An essay on the relativity theory and the theory of quanta.

STATISTICAL ABSTRACT OF THE UNITED STATES, 1920. Pp. 874. Washington: Superintendent of Documents, Government Printing Office. Price, 50c., paper covers.

THE SILVER BROMIDE GRAIN OF PHOTOGRAPHIC EMULSIONS. By A. P. H. Trivelli and S. E. Sheppard. Pp. 143, illustrated. New York: D. Van Nostrand Co., 1921. Price, \$2.50.

This is the first of a series of monographs on the theory of photography from the research laboratory of the Eastman Kodak Co., edited by Dr. C. E. Kenneth Mees and Mrs. Mildred S. Schramm. It presents the results of a complete crystallographic study of the grains of high-speed emulsions which showed that all the grains belong to the same crystalline class and that consequently their formation in the emulsion could be studied in the light of von Weimarn's dispersion theory.

PAMPHLETS

THE ENGINEER AND THE UNIVERSITY. New York: Columbia University, 1921.

An interesting and attractive presentation of the engineer's status in industry, of the problems involved in his education and of what the School of Mines, Engineering and Chemistry of Columbia University has to offer toward the solution of these problems.

INTERFACIAL TENSION MEASUREMENTS AND SOME APPLICATIONS TO FLOTATION. By Robert B. Elder. Pamphlet No. 1, Bureau of Mines and Geology, State of Idaho, published in co-operation with the U. S. Bureau of Mines. Moscow: University of Idaho, 1921.

A mathematical consideration of the Du Nouy and Fahrenwald methods for measuring surface tensions and their application to flotation problems.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7. More than 100 manufacturers will exhibit their latest gas-burning appliances.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting at Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING is holding its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

NATIONAL SAFETY COUNCIL will hold its tenth annual conference at the State House, Boston, Mass., Sept. 26 to 30.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

The Chemical Exposition

THE Seventh National Exposition of Chemical Industries has gone into history, and when we consider the dullness of the times and the depression in all trade we can use the record to prove that chemical industry in the United States is alive. It is true that some of the exhibitors who usually make great displays reserved their space but showed no wares, merely equipping their booths as offices and reception rooms. Of these, however, there were but few, most exhibitors making their usual displays.

Although the trip to the armory at which the Exposition was held involved a long and weary journey—far beyond the Polo Grounds, which is “farthest north” for any but the most intrepid patrons of New York’s rapid transit system—there was an attendance only slightly smaller than was recorded at Grand Central Palace last year. The immense floor of the armory provided ideal exhibition conditions and exhibitors seemed to be well satisfied not only with the number of spectators but with the volume and character of the inquiries. It was a quality crowd. Far fewer “literature hounds” overran the premises. By the same token, fewer inquiries came from entire strangers. Most of the callers were old friends and visitors looking for valuable improvements or innovations.

It will be good news, however, that by a large majority the exhibitors voted to hold the 1922 Exposition in the old quarters at Grand Central Palace. This more convenient location, nevertheless, has the disadvantage of its merit in that the crowd of visitors becomes almost unmanageable and the vast number of curiosity seekers makes it difficult for interested persons to get information. Something will have to be done to regulate the attendance and restrict it to an appropriate class.

It will be news to many, as it was to us, that the plan to remodel Grand Central Palace into an office building was never consummated. Accordingly the building is still available for expositions, although a year ago its owners officially declined to consider the Chemical Exposition for 1921 on account of the proposed change. This forced the Chemical Exposition management to look for new quarters, resulting in the selection of the armory.

On the whole the Exposition was a great success. Some criticism could be recorded, but most of it pertains to the matter of location, which will not be a bothersome factor next year. All things considered, there was little complaint, although we have not yet heard from those who deftly purloined from the exhibit of the U. S. Industrial Alcohol Co. bottles of clear water-white liquid labeled “Ethyl Alcohol” but containing *aqua pura*. Doubtless when those individuals fondly began to mix their cocktails they concluded that the Exposition was a snare and delusion.

The Shoemaker And His Last

ANNUALLY for several years past there has been some mild talk on the part of a few exhibitors at the Chemical Exposition in favor of organizing for the purpose of holding and controlling an exposition of their own. Apparently the thought was inspired by a feeling that the Exposition Company was growing rich at the expense of the exhibitors and that the latter might as well run their own exposition on a mutual basis, and benefit accordingly. Perhaps this type of reaction and line of reasoning are natural enough, but we doubt if the reasoning is sound and logical.

We hold no brief for the Exposition Company. In fact we know nothing of it except through contact with its two managers. But we think it is possible by giving a little thought to the subject to see the futility of such a proposal as has recurred with the close of each exposition. The conduct of expositions is a business, just as the manufacture of chemical equipment or the publication of a chemical magazine is a business. It requires money, brains and organization. Expositions do not spring into full-fledged existence over night, nor do they manage themselves. Somebody works the year round on the Chemical Exposition.

There is no reason to believe that an association of manufacturers conducting their own exposition on a mutual basis could achieve the results of the last seven expositions without resorting to the same means that have made those expositions increasingly successful. If a mutual organization of manufacturers were to attempt to conduct their own organization they would find it necessary, first, to provide the money through subscription to capital stock; second, to employ skilled and experienced exposition managers to conduct their business for them, and third, to devote considerable time to the conduct of the association’s affairs. If there is anything attractive in this scheme it is not apparent on the surface. The net result would be additional burdens and inevitable disappointment and dissatisfaction due to attempting something entirely outside the training and experience of those who would undertake the task.

The whole conception is based on an industrial fallacy. Extended to its logical limit, it would involve each man doing everything for himself instead of allowing a specially qualified man to do one thing for a large number of us. That the promoters of the Chemical Exposition have made money is not to be doubted, otherwise they would not have continued in the business. Presumably the same is true of every exhibitor in his particular line of business. Business ventures succeed and make money because they render a service—real or imaginary. The Exposition Company has taken advantage of a great opportunity, but we believe it has also rendered a real service. If that service has not been all that it should be, there is no more cer-

tain way of improving it than by frank consultation and co-operation with the management or its advisory committee. No permanent good can be accomplished by holding aloof or indulging in carping criticism.

If we may judge from the way in which space has already been taken for next year's show, we may justly conclude that the proposal for exhibitors to hold their own exposition will make no substantial headway, and we hope it will not. Let the shoemaker stick to his last. If there is no satisfactory reason for the existence of the present Exposition, certainly none can be advanced for a substitute. We believe that the Chemical Exposition Company has a useful purpose to serve and that it has shown itself worthy of the support of the chemical industries. That the management has made mistakes there is no doubt; but it is equally certain it has been open to constructive criticism and has acquired experience that can only be increasingly useful as long as chemical expositions are held.

The Rubber Industry And the Planters

WHEN an American visualizes the word rubber he thinks of factories, tires, tubes, belts, hose, etc., for our end of the rubber industry is manufacturing. But in Europe, particularly in the British Isles and Holland, the reaction is entirely different. Your traveled Englishman will think of countless waving trees among which flits the inevitable coolie with his can of latex, for the British are the planters.

Taking the year 1919 rather than 1920 as a basis, a study of statistics shows that the United States consumed 68 per cent of the world's production of rubber, which amounted to 339,000 tons. The production for 1920 was 368,000 tons, practically 89 per cent of which was produced on the plantations of the Far East. Our British cousins own about 75 per cent of the plantation acreage, which in 1919 reached a total of 2,181,000 acres in bearing with 730,000 acres yet to come in. Their investment amounts to about \$300,000,000, of which by far the larger portion is held by small investors throughout the British Isles.

America therefore stands as best customer to the plantation industry. About 70 per cent of the rubber consumed in this country goes into tires and tubes. Consequently anything that affects the tire industry is soon the cause of no little concern in Great Britain. Unfortunately for the planters, their business has been built on a steadily rising American demand. When that demand is curtailed or cut off, there is no other market in which to dispose of the surplus. The situation from the Britisher's point of view has been rather well summarized by H. P. STEVENS in a recent issue of the *Journal of the Society of Chemical Industry*.

The chief difficulty is that our friends the planters have developed practically a one-market business. The depression of 1920-21, which played such havoc with our one-product tire factories, naturally raised Ned with the price of plantation rubber, which dropped from 40-50c. per lb., the normal price range of 1918-19, to 10-15c. This is considerably below the cost of production, which has been variously estimated at 18 to 25c. per lb. These are facts. The question is what to do about it.

The planters, through their association, are curtailing production. Their plan is evidently to produce only enough rubber to meet the demand. This will help, but will not furnish a complete remedy. The American

depression, coming as it did from real and not imagined causes, cannot be expected to have a short period of convalescence. The recovery will be slow and gradual, and has been estimated at from two to five years before normal conditions will be reached.

The remedy for our one-product tire factories is to diversify, play to more than one market. The advice applies to the planters as well. Tea, coffee and other tropical products should be made a regular business and not a side line. In fact there appears to be no reason why the planters cannot turn their attention to cultivating other trees and shrubs yielding valuable materials such as the alkaloids and even the tannins.

For several years past the Rubber Growers' Association has offered handsome prizes for new uses for rubber. To date we know of no awards having been made. There are plenty of new developments under way, but they are the outgrowth of a definite demand. Most of these schemes have still several years of research ahead of them. It is possible that new uses will be developed, but not soon enough to have a serious effect on the market for the next five years.

All credit is given the planters for the high quality of plantation rubbers, but it will be admitted by practically all American rubber technologists that there is still something lacking. Fine para (true up-river fine) is still the best rubber produced in point of (a) uniformity in period of vulcanization; (b) nerve; (c) elasticity and tack; (d) viscosity of cement, and (e) life. These properties could be elaborated to considerable extent. Suffice it to say that the ignorant *seringueiro* of the Amazon country, who prepares his hams by a method passed down to him from the ages, produces a rubber in many ways superior to the finest product of the scientifically controlled plantation.

Superior cleanliness, constancy of supply and reasonable constancy of product, coupled with price, have been in favor of the planter in his battle with the wild rubbers. Research has been practiced on the plantations, but many things of little importance have been magnified far beyond their deserts. Isn't it time that an effort be made to get at the fundamentals of rubber production and to produce a superior product?

The Psychology Of Business

SOME keen observers of business conditions and trends have lately been expressing the opinion that business has become ripe for a decided turn for the better. They base their opinion not so much upon the concrete underlying facts as upon their appraisal of how men's minds will act. The lapse of time since business got into the dumps is a prominent factor. In war time it is shown that it is not in the nature of the human mind for the owner to be scared continuously. It is a feeling which the normal individual cannot hold steadily. The average business man, according to the view of many observers, cannot remain indefinitely in a lethargic condition, or in a condition of waiting. When prices began to decline, some manufacturers decided to shut up shop, and some even declared that they would not reopen until they got their price. After a time the condition of a closed factory grew irksome to the owner and he became disposed to make some goods even if it was not certain he could make money.

It is supposed to be a distinctly feminine trait not to assign the real reason for an opinion or course of conduct. That may not be the case with business men,

yet an observer can see that business men do something not altogether dissimilar in making selection of different sets of facts from one time to another to find a reason or an excuse for a line of conduct. The facts selected may be hard, even statistical, the selection, however, being due to the mental state.

From the great mass of business facts available one can, as a matter of fact, make selections that will be decidedly encouraging or decidedly discouraging, and if the selection is dictated by the mental condition, psychology rules conduct, even though statistics are paraded as the basis. One may say that business is very bad, for there are 5,000,000 persons out of employment, but one may also say that business is not so very bad and there must be a considerable volume of buying power, since 35,000,000 or 40,000,000 people are in employment. One may say that money is tight and collections are poor, but it may also be observed that a great many payments must be made, since the Federal Reserve Board reports debits to individual accounts at banks running only 15 or 20 per cent below those of a year ago.

There really is little difficulty in selecting a collection of facts that will justify a line of conduct in business when psychological conditions have settled the question whether the individual desires support for a policy of "taking hold" again or of waiting still longer before doing anything.

Now it is an actual fact, which everyone has had opportunity for years past to observe, that when business improves the reasons for the improvement are cited, in facts that already existed, and then many exclaim, "Why didn't we think of that before?"

Already there is some improvement in many lines of trade, and we may now look forward with confidence to the reasons for the improvement being duly set forth, after the fact. A year ago practically everyone realized that business and prices would have to be cast in a new mold, a process that would take time. Now we are ready to wake up to the realization that a year has elapsed, a year of great readjustment.

The Oppau Explosion

OUT of the chaos of newspaper misinformation gradually comes what seems to be a rational interpretation of the disaster at Oppau, Germany, which resulted from an explosion at the Haber nitrogen fixation plant located there. We are finally informed through press dispatches that it was an "explosive" which caused the damage and that it was not a huge tank of nitrogen which by its "explosion" caused the disaster. Also the mysterious new gas which was being compressed but whose "properties were not known" is no longer the guilty party even in the most garbled guesses of the layman.
